It is no new fact to be told that, where protection is efficient both from fire and grazing, the natural growth in the Forest Reserves of the Presidency is excellent; and on the contrary, where it is not so, the natural growth is poor. All that the Forest Officer has to do, therefore, is to protect—and possibly direct

* The surmise is correct. See Yule's *Hobson-Jobson* s. v. "Brinjal" for the curious history of the word.—Ed. T. A.

by improvement cuttings—and leave Nature to do the rest. Protection from fire, the Board of Revenue observes, is a mere matter of money and labour, but to combine protection from grazing with the necessities of the ryot and the grazier is more difficult. An instance of the good results of effective protection is given in the "marvellous growth," in the Anantapore reserves, which are specially protected by stone walls. The question, therefore, which arises for consideration is should not more be done in the way of fencing? The difficulty has been the matter of cost, but, as the Board remarks, if railway lines can afford to be effectually fenced, there would seem to be no reason why forests should not, at any rate where the forests lie in large compact blocks. "Such fencing," the Board continues, "would assist most materially to protect both from fire and from thieves; and with protection from the latter, all the obnoxious transit rules could be abolished."

To show the effect of protection on natural growth, the case is mentioned of the Peddapalee forest in Vizagapatam, which has been under special protection for five years. In Nellore, in the Srikarikot forest, experiments were made to increase reproduction by cutting the roots of the eugenia jambolans, and the result is reported to be satisfactory, many shoots having come up. Experiments were also made in the felling of casuarina trees in Nellore, and it was found that the best season for coppicing was from September to November, and that the coppice was best when under shade and when the length of the stem left was not less than 4 feet. In Cuddapah, the growth of red sanders from seedlings is reported to have been successful; the ordinary bamboo seeded in most parts of Cuddapah and in the Nallamalais of Kuruool. In the Nilgiris, the reproduction in the sholas and the growth of coppice shoots in the *eucalyptus* plantation are reported to be satisfactory. The reproduction from seed of bamboos in the Nagalapuram reserve in Obingleput, the germination of sandal wood seeds in Saleu, the reproduction from coppice in the Sholakarai, block in South Coimbatore, and the growth of kongoe seedlings in places where clean cuttings have been made in the evergreen forests of Tinnevely, are reported to be noteworthy. In the Tindivanam and Vilupnam ranges in South Arcot reproduction by coppice is said to have failed owing to the unfavourable character of the season; the coppice from casuarina shoots in the Cuddalore range was also a failure. In North Arcot and Saleu the growth in the open areas is said to have been very poor, chiefly owing to over-grazing. In the mixed high forests of South Coimbatore, in several of the valleys and hill slopes in Madura and in parts of North Malabar, the unsuitable nature of the soil and the thick under growth of grass and thorny shrubs have retarded natural reproduction.—*Madras Times*.

THE CEYLON MARGOSA: A HINT!

There are few people among the many English in Ceylon who do not know the margosa tree (*Por. margoera*, and Tamil *vepum marani*), but to many it is only known as a very fine "shade" tree, one that reared successfully, and treated with common generosity, will fairly last a century, and even more. It yields first a rough bark or outer bark which Tamils have only lately begun to value as a rival to quinine, in fever cases,* though administered very sparingly and in small quantities its taste being intensely nauseous and bitter. Its leaves also are medicinal and when burnt green on a fire in a brazier or earthenware chattie (as well as the dead bark) will, if placed in any room, drive away or kill the most obstinate and bloodthirsty mosquitoes. The green bark is also successfully used as a "verruifuge" in the treatment of buffaloes and country cattle, and pounded and applied to a sore will kill off every worm in it. The timber sawn from this tree is noted

* Trees in Colombo were barked to death forty years ago, just as *Cassia fistula* trees are being destroyed now.—*Ed. T. A.*

for keeping off white-ants. A valuable and particularly clear gum exudes from the bark, naturally in small quantities, but when bruised in large sheets and yellow drops like icicles! Books bound with this gum are never bored or eaten by worms, and "painted" on an abrasion or skin wound will take off all pain. The yield of the tree in the shape of [fruit is marvellous, and these furnish food to crows, goats and hundreds of the smaller of the feathered tribe, and the ground under margosa in fruit is daily and nightly carpeted with fruit. The leaf or seed of the margosa contain a valuable, rich and clear oil, sometimes burnt in earthen lamps, but specially valuable for fly blown sores in horses, elephants and cattle.* It is also used medicinally in very minute doses. It smells atrociously, but is very valuable as a lubricant for steel, iron, &c., from which it keeps rust, and would doubtless answer well as a lubricant for machinery and rolling gear. It is generally sold in the markets at 75 cents a quart bottle (*Ceylon quart*), being expressed in rough wooden mills, chekkus or by pounding, but when treated in a superior oil mill might be worked cheaply; but once a mill has worked for margosa oil it becomes practically useless for anything else. R. A.

PACKING ORANGES BY STEAM.

EDITOR "FARMER AND FRUIT-GROWER."

If one wishes to see systematic orange packing it will repay him to look in and see Mr. Sampson, at Boardman, with all his practical methods. He uses a steam motor to propel a three-hank Ayer's Sizer and many wrapping machines. One man is constantly and easily turning trays of oranges into the hopper of the sizer. Two men, one standing on each side of the hopper, assort the oranges. The seconds all go to the sizer on the left, the firsts to the two on the right. He has no russets, and hardly more than 10 per cent. are seconds. Here you can see a machine which comes near to a living, moving being, which responds promptly to the will of the operator and supplements his intelligence. Under such a man as Mr. Sampson, who has the genius to know a good thing when he sees it and get the best work out of it, who actually compels it to do only the best work, give me the Ring Chain Sizer. From the sizer, like drilled soldiers on the parade, the oranges steadily move on to where the wrapping machine picks them up, prints on each wrapper the brand of the grove, neatly and securely twists the wrapper around the orange and then deposits it in the bins where the packers are arranging them in the clean cases. This machine wrapping is done with such care that eggs would go through the same process uninjured.

TEA IN FOCHOW.

We have been forestalled in a rejoinder we intended to publish to Merchant's letter of 29th ult., by the writer of a 'communicated' article on the subject of the letter. As he happily hits upon the points we purposed bringing forward, there is no occasion for us to write at length about them. The points are simply these: *First*, that the real reason of manure not having been used on the tea gardens is, that it was not procurable in sufficient quantity. We gave this as a reason on the 16th January in an article headed 'Tea Prospects,' on the information obtained from upcountry tea men in an interview we had had with them, and it should be noted that they did not oppose the use of manure; they merely stated it was not procurable. *Second*, The idea of using chemical manures had never occurred to them. They had never heard of them. But we have to ask, who knows what they would do if the advantages were

* And in lieu for mercury for killing maggots in wounds or sores in the human subject.—*Ed. T. A.*

thoroughly explained to them by an influential body? We should like to add to 'Merchaet's' proposal, that head representative teamen from the country should be invited to attend the conference. It is to the interest of the Cantonese to keep us apart as long as possible from direct communication with the upcountry men, and here is a chance and, good reason, for our trying to break through a custom which suits our Southern friends so well.

From an upcountry teaman with whom we are well acquainted and who has come down to see after his unsold stock here, we learn that several of the teamen are very much against the proposal to make small chops next season on the grounds that it would add so much to the expense of preparation. We do not quite follow his explanation as to how this comes about, but as he asserts that a large pile of tea can be fired at the same expense as a smaller one, both being contracted for as a day's work, we suppose we must accept the statement as correct. We were glad to have our information on the subject of early firing, lately published, confirmed. Instead of allowing the tea to stand about for a long time as heretofore, it is to be fired as soon after picking as practicable. On the subject of supply, he stated, in reply to our enquiries, that the quantity would depend upon the extent of the advances made by the Hong here, but he had reason to believe that it would fall considerably short of last year, as neighbours in the country had told him that they were unable to get their customary advances made them. He said that loans, and credit generally will be greatly restricted this year.—*Echo*.

PROTECTION OR DESTRUCTION OF BIRDS IN INDIA.—Our correspondent Jes. H. B. will be interested in what follows:—

Mr. W. L. Selater contributes to Indian Museum Notes an interesting little article on the economic importance of birds in India, with special reference to the question whether legislation is necessary to protect insect-pest destroyers. Of the birds destroyed in this country for plumage or food, very few, if any, he states, are insectivorous; while, with regard to those of mixed diets, it would be inadvisable to protect them, "since they may do much greater harm in devouring fruit and grain than they do good in destroying insects," as is especially the case with crows and starlings. The principal birds killed for their skins and feathers, which are exported at high prices, are egrets, and the cattle egret, the pond heron and the blue heron, while the snake-bird has feathers of a certain market value. The lengthened scapular feathers of this bird, which are the only ones sold for export, are looked on, we learn, "as a badge of royalty by the Khasias, and were once the badge of one of the Bengal regiments of irregular cavalry." Of pheasants, many are exported in large quantities; the bulk of the specimens brought down to Calcutta being shot in Bhootan and Nepal. The Sikkin and Simla Argus pheasants are probably largely exported, but, as the writer says, neither is the true Argus, which is a bird found only in the Malay Peninsula. Indian parrots, the blue jay, the kingfisher, and jungle-fowl are the only other birds which are exported in large quantities. Mr. Selater quotes from Mr. Hume's "Gleanings from the Calcutta Market," for the list of birds commonly eaten in India, and sold in the markets of Lower Bengal. They include the snipe, snipplet, plover, teal, and the red-crested pochard. Of the birds shot by European sportsmen and eaten, but which are not common in the Calcutta bazaar, are the green and blue rock pigeons, the bustard, the florikin, the Sarus crane, the hee-stalk bird, the ortolan, the sand-grouse, the peacock, jungle fowl, gray fowl, the red spur fowl, black partridge, painted partridge, the kyah partridge, and the gray quail. Mr. Selater adds a list of purely insectivorous birds but none of those we have mentioned fall within this category.—*Indian Agriculturist*.

THE FAN PALM.—REV. C. B. Henry states that the fan palm of China grows only in the San Ui district, twenty miles long by ten miles wide. The trees do not yield leaves suitable for fans until six years old. Some trees are said to be over 100 years old, but the tallest measure only about twelve feet. From April to November the leaves are cut monthly, one to three being taken from each plant. From 10,000 to 20,000 people are employed.—*Florida Agriculturist*.

COFFEE AND COCOA IN PANAMA.—Attention is being paid (says the London *Grocer*) to the planting of cocoa and coffee, etc., in Panama, one company having a large number of the young plants of the various classes mentioned, and which are in a condition of vigorous growth. Good tobacco has already been produced by this company, and the crop well cared, was manufactured into cigars of a fair quality. There is scarcely any doubt as to the success of the experiments in the cultivation of cocoa, although several years must elapse before the results can be properly estimated. With coffee, of which about 15,000 plants have been set out during the year and carefully attended to, the outcome is more doubtful, as the conditions of soil and climate are not favorable. The ground on which this essay in coffee-growing is in progress is only about 250 feet above sea level (an elevation not sufficient in this latitude) while the soil has but slight depth of loose vegetable mould, resting upon a stratum of red friable clay, which has for its base the talpate of the country—a compact indurated clay or rock, impervious to water and into which the roots of the plants cannot penetrate. A company has also been formed for the cultivation of sugar-cane and the manufacture of its products, but it has not yet passed beyond the stage of mere organization. It is doubtful if there are good lands for the growth of sugar-cane in the immediate neighbourhood, although there are in the department; but tobacco, rubber, cocoa, and textile and medicinal plants may be cultivated to considerable extent at great profit.

TEA, COFFEE AND CINCHONA IN JAVA are thus referred to in the *Straits Times* of 26th March:—

Last year has been disastrous to tea planters in Java owing to a prolonged drought which resulted in the young plants, from one to three years old, dying in hundreds of thousands. It will take years to repair the damage done. The crop fell in consequences far short of that of the previous year. The planters as a set-off against this stroke of ill luck, have managed to persuade the Government to order the supplying of the army in Java with locally grown tea. This has aroused the attention of the Chinese to that branch of planting industry. They consequently have got hold of several estates by entering into contracts with the owners to enable these Chinese to prepare and bring to market Java tea. It seems that small estates have larger working expenses than bigger and more productive plantations, and, hence, have need to call in Chinese aid, as the Chinese can draw larger profits from estates under their control by means which few Europeans will resort to. Another result of this passing over of estates into Chinese hands is that the European capital and labour expended on them now benefit Chinese owners. In West Java, Liberian coffee is coming into greater favour for cultivation than the Java article owing to climatic conditions giving the African berry the advantage, provided the ground be not too high lying. Liberian coffee now readily finds buyers at Amsterdam, and also in America. Fair Java it is said brings at the utmost 54 to 54½ guilder cents per picul while Liberia fetches 56 cents a picul. Cinchona growing in Java has proved highly unprofitable from the heavy fall in prices. Experts differ whether the decline is due to overproduction or to speculation for a fall, but agree that its continuance will prove calamitous to this kind of cultivation.

MANGROVE PLANTS FROM CEYLON FOR THE ROYAL BOTANIC SOCIETY OF LONDON.

The *Standard* of 14th March has the following:—
At a meeting of the Royal Botanic Society, held on Saturday, Mr. J. Bell Sedgwick in the chair, the Secretary announced the safe arrival at the gardens of a number of young plants of the mangrove, from Colombo, remarking that, though common enough in the mangrove swamps of the Tropics, this plant had never yet been grown in England, though many attempts had been made by the Society and others. In the conservatory, however, the white mangrove, a somewhat allied plant, had been growing for the last eight years, but the rate of growth was very slow, and the plant appeared very delicate.

INDIAN TEA SALES.

(From *Watson, Sibthorp & Co.'s Report.*)
CALCUTTA, March 16th, 1892.

There was a good demand at about previous rates in the sales held on the 10th instant. The Bombay buyers were very keen and suitable teas realised from one to two annas over present London prices. 4,712 packages changed hands.

The season is now practically closed. Since it opened on the 14th May last 30 series of sales have been held at which 433,678 packages changed hands at an average of A. 6-8 or about 9d per lb. as compared with 391,990 packages sold in 34 sales in season 1890-91 at As. 7 or about 10½d per lb. and 466,784 packages sold in 38 sales in season 1889-90 at As. 7-7 or about 10½d per lb.

The increased demand from various new outlets during the past season was one of the prominent features of the market, and prices realised for suitable teas were throughout very considerably above current London rates. There is no doubt, in this regard, that if this market had been more liberally supplied the growth of the trade with these new consumers of Indian tea would have spread even more rapidly than it has done. In future a much larger proportion of the crop should find a market here as these recently found customers ought to be encouraged and others from still future fields induced to complete. The figures published by the Indian Tea Association on the 12th instant, lend additional weight to the above remarks, they show that from the 1st May to the 29th February in the season under review the exports from here to all other places than the United Kingdom were 8,620,000 lb. as compared with 5,764,000 lb. in 1890-91 and 4,939,000 lb. in 1889-90.

The average price of the 4,712 packages sold is As. 4-6 or about 6½d per lb. as compared with 7,528 packages sold on the 26th Feb. 1891 at As. 7-11 or about 10½d per lb. and 7,637 packages sold on the 27th Feb. 1890 at As. 5-4 or about 7½d per lb.

The exports from 1st May to 14th March from here to Great Britain are 109,511,071 lb., as compared with 98,179,163 lb. at the corresponding period last season.

NOTE.—Last sale's average was As. 4-11 or about 6½d per lb.

EXPORTS, STOCKS, &c., OF INDIAN TEA.

	1892. lb.	1891. lb.	1890. lb.

NOTES ON PRODUCE AND FINANCE.

ADVICE TO GROWERS AS TO QUALITY OF TEAS.—Messrs. Stanning, Inskipp & Co. have issued the following circular with reference to tea season, 1892-93:—In view of the approaching manufacturing season, we beg to offer a few remarks for your consideration. The fact that common and medium grades have sold with difficulty for but little more than half the prices ruling at this time last year, must be a source of anxious concern to producers. This heavy depression is due to excessive quantity and poor quality, and to the sudden and enormous increase in the imports from Ceylon. Fine and finest have been rather scarce throughout the season, and have sold readily at satisfactory prices. Ceylon teas have shown some falling off in quality, but the demand for them has about kept pace with the import, as will be seen by the figures for the last nine months, viz.—Import, 46,630,000 lb; Delivery, 45,235,000 lb. The imports from all India for the season will probably average 3 1/2 millions per month, and the deliveries half a

million of pounds less, giving an excess of supply over demand of about 6 million of pounds. The stock of Indian in London at the end of February last stood at 47,558,000 lb. or more than five months' consumption. Under these circumstances it would seem that, while avoiding the danger of plucking too fine, the only course open to growers is to improve the strength and flavour of their teas, and thus make them more attractive. We think this may be done by plucking moderately; by getting the leaf off in good time—that is, before it has become hard and coarse—and by giving the closest possible attention to the manufacture. We also think the endeavour should be to produce a fair proportion of true Pekoe and broken Pekoe, which would reduce the quantity of "medium," and help to bring up the average price. The export from China appears likely to still further fall away in the future, the teas being in disfavour, owing to their continued inferiority, and the blow the industry has sustained in consequence must be held in mind by Indian and Ceylon planters, who should not allow quality to be their first consideration, or prices may sink to a point below cost of production.

TEA FROM NATAL.—On Monday Messrs. Gow, Wilson, and Stanton offered 303 boxes of Natal tea, containing about 15,000 lb. from the Kearnsay estate. The prices averaged 5d per lb. but we imagine that the Natal growers sent their first large consignment more with a view of testing prices than making regular shipments, as there is a good market in South Africa for their tea. Fears of the failure of the coffee crop seem to have first prompted the Natal colonists to seriously contemplate tea cultivation, but although a few samples were obtained from Kew many years ago, the actual beginning of the industry seems to have been only made in 1877, when Assam hybrid and Assam indigenous seed were imported from Ceylon. Since that date steady progress has been made, and even in 1884 the Assistant Executive Commissioner of Natal reported that over 50,000 lb. were produced and disposed of locally. The rainfall is low for a tea-growing country, but this is supplemented by such excessive snowfalls that its want is not several felt, and the fact of the cultivation thriving is a strong testimony of the adaptability of the colony for the purpose. The tea is grown near the coast where the loam is light.

LAST WEEK'S TEA MARKET.—There has been a smaller quantity of Indian tea brought forward at the public sales, namely, 24,763 packages against 34,900 packages in the preceding week, says the *Produce Markets' Review*. This diminution in the quantity has not, however, improved the low quotations of common tea to any extent, although at the later sales a slightly firmer tenancy was noticeable. However, as the supply of these grades will probably continue to be quite sufficient to meet the declining demand for them, there appears no immediate prospect of any reaction of importance in prices. The demand that prevailed some time ago for common kinds appears to have fallen off considerably, and it is evident that the consumer is prepared to give a fair price for good tea. For the medium grades there is a good enquiry, and, as the proportion of these is gradually getting more restricted, their value has been well maintained. Finest descriptions are eagerly competed for, and sell readily with an upward tendency, especially the finer Darjeelings, which have fetched extreme prices. The public sales of Ceylon teas have again been remarkably small, but, as the demand has not been good, there has been little variation in values. The finest grades, both of whole and broken tea, are still in request, and their value is fully maintained, but medium grade Pekoes, worth 8d to 10d, are rather easier. There has been a slight increase in the demand for common teas, at last week's quotations. A material contraction in the supplies at auction has been noticed this week, says the *Gleaner*, the total quantity put up not exceeding 25,010 packages, in comparison with 31,660 packages previously, but at the resumption of business on Monday this diminution in the offerings of Indian teas did not appear to have a

reassuring effect upon the market, which was in an almost demoralised state, many invoices being withdrawn where no biddings could be elicited, and most of the tea that was sold showed it to be as cheap, if not cheaper, than ever. This remark, of course, refers more particularly to teas of a common grade, as all preferable kinds met a fair competition at full rates. The *Grocers' Chronicle* says:—The depressed prices latterly observable in this market are no doubt entirely due to the excessive supplies which have been unloaded upon it, without reason, during January and February. Last year, during those two months, 290,736 packages Indian and 106,232 packages Ceylon were offered in public sale, at a time of unusual activity and on a rising market, whilst the country dealers were laying in stocks in view of higher prices. This year the situation has been quite the reverse. Trade in the country has been depressed; prices have been on the down grade—every week registered a lower range of value, yet the importer kept steadily on crushing the market, in order to get out himself; and it now appears that 295,416 packages Indian and 133,634 packages Ceylon tea have been offered during January and February, or 42,672 packages in excess of last year, when the trade was booming. Yet the importer deprecates the want of animation in the market now and the selling brokers write mournfully that no improvement can be noted. There is just the shadow of a better feeling this week end, owing to the smaller sales. Buyers are not so entirely disheartened, and they argue that once the London market shows a slightly improved tone country dealers would begin to operate again.—*H. and C. Mail*, March 4 lb.

LAST WEEK'S TEA SALES.—The diminished supply of Indian tea brought forward at the public sales has been sufficient to meet the demand, and consequently the market has shown no improvement of importance in price, although the tendency is slightly firmer, says the *Produce Markets' Review*. The statistical position is stronger than in the preceding month, the surplus stock being 3,000,000 lb. smaller, or 7,000,000 lb. against 10,000,000 lb. A stock, however, of 47,000,000 lb. at this period of the year is sufficient to prevent any material upward movement, especially in the lower grades, although these kinds are from 30 to 40 per cent below the prices of last year. The deliveries for February were satisfactory, but even at this rate there will be an available supply, with the additional imports to arrive, of fully five months' consumption. Therefore, should the coming season be later than usual, owing to climatic causes, there will be ample tea to meet requirements, although some of the hotter grades may arise to a higher level, in consequence of moderate supplies. There is little change in the position or value of Ceylon teas. The supplies have been larger than for some time past, but the dealers were rather bare of stock, and have easily taken the extra quantity offered. The only kind of tea in which any perceptible change has taken place is broken tea worth from 10s to 1s, which may be noted rather easier.

THE IMPORTS OF PRODUCE.—The Board of Trade Returns for February are again unsatisfactory from the home trade point of view. The imports are valued at £34,877,931, an increase of £1,568,577, or 4.7 per cent; and the exports of British and Irish produce at £19,328,753, a decrease of £1,141,868 or 5.5 per cent. Thus, allowing for the extra day, the imports are about equal to those of February, 1891, while the exports are nearly £2,000,000 lower. The increase of the imports is to be found in articles of food, and cereals in particular. The consumption of tea reached 17,162,349 lb., compared with 16,024,078 lb. There is a considerable falling off in the receipts of sugar. In February 1891, the imports from Germany, Holland, Belgium, France, and the United States amounted in the aggregate to 827,379 cwt., but in February of this year the aggregate from those countries is only 555,627 cwt. On the other hand, in February of last year

Russia only sent 1 cwt., but in the same month of this year the receipts thence were nearly 164,822 cwt., and for the two months the receipts are 314,436 cwt., compared with 1,201 cwt. Of raw sugar the falling off is chiefly found in beet.

COTTON PICKING BY MACHINERY.—A company has been organised at Chicago, with a capital of 5,000,000 dol., to manufacture a new cotton-picking machine, which, an American newspaper says, will do the "work of seventy negroes, and make an interesting change in the negro problem of the South." Indeed, says the authority we have quoted, "unless all signs fail, this company is destined to revolutionise the cotton industry."—*H. and C. Mail*, March 11th.

GIBBS' PATENT DRYER AND PURE AIR FURNACE.

The improvements recently effected by Mr. W. A. Gibbs in the design of his filter stove and dryer have rendered this combination popular with tea planters, and given a decided impetus to the sale. The first great economy of the system is in the novel principle of the stove, which allows of the direct utilisation of all the products of combustion from any kind of fuel, as testified by the reports of those who have adopted it. Another point of economy is that damp fuel may be burnt with advantage instead of loss. It is well understood that in the ordinary form of up-draught furnace, any moisture in the fuel used is converted into steam, which wastes a large part of its heating value, but in this furnace the products of combustion being drawn down through the fire, instead of passing away from the surface, any water in the fuel is decomposed into oxygen and hydrogen, both on which, in burning, add to the heat of the resultant air. The second notable feature of the apparatus is the sifting arrangement, whereby the finest tea (dhoob-gari) passes out of the dryer previous to the delivery of the main bulk, thus avoiding any over-drying of the most valuable qualities; this process has proved very advantageous, and will doubtless be appreciated by all practical tea makers. Attention is specially directed to the improved sifting arrangement recently introduced by the patentee, i.e., the substitution of woven wire panels (of two different sizes of mesh) in the body of the machine for the original extra drum on the end of the cylinder. The advantage of this arrangement is that the tea is sifted out in two degrees of fineness, and any desired variation can be made in this respect by simply inserting panels of coarser or finer mesh; and further, if at any time it should be desired to dispense with the sifting operation the screens are easily replaced by cover plates. By reason of these recent improvements it is now generally acknowledged that the Gibbs' Dryer manufactures a very large quantity of tea under conditions that are remarkably economic in regard to labour and fuel, that the mechanism is durable and simple, and that last, but not least by any means, is the important fact that the perfect distribution of the heated air currents ensure absolute regularity of quality without these necessity of skilled labour. With these important points in its favour it is not surprising that the dryer and stove are making rapid headway, and that planters in India and Ceylon bear testimony to their value.—*H. and C. Mail*.

THE CINCHONA BARK MARKET.

The present ruinous state of the bark market is caused by over-production, not only is the market over-loaded with stocks, but the present rate of production exceeds what is required for consumption.

Producers, however, have the remedy in their own hands, supposing that they were to destroy all bark yielding under 3 per cent of quinine, or more than one-third of the total production, what would be the probable effect on prices?

The following are the shipments and figures roughly for 1891:—

Shipments from	Lb. English	Under 3%	Percentage	Remaining for shipment
Java for 1891	8,000,000	2,240,000	28 %	5,760,000
Ceylon "	6,000,000	4,000,000	67 "	2,000,000
India "	4,500,000	2,025,000	45 "	2,475,000
	18,500,000	8,265,000		10,235,000

Bark unlike other produce will keep for years. Lately some Cuprea, which was imported years ago, was put up for sale at a London auction.

If large quantities, especially of the poorer kinds, are thrown on the market, they are bought up by speculative manufacturers or speculators and stored for use in the future, or to be resold in case of a rise in price.

The effect of this is not only to depress prices for the present but to keep them down for years to come.

There is the danger, too, of a combination among buyers.

This state of things can only be prevented by producers destroying, instead of shipping, their poor barks: thus producers have the remedy in their own hands.

The present slight rise in price is caused by the increased demand for quinine owing to the influenza epidemic. When this demand ceases, will not prices fall back to their former level, or even lower?

Ledgeriana bark gives an average of 4 to 5 per cent of quinine.

Succirubra and other kinds, good renewed, an average of over 3 per cent of quinine.

Succirubra and other kinds, bad renewed (that which has been renewed over 3 times and has become "corky" and fibrous), under 3 per cent of quinine.

Succirubra and other kinds natural an average of under 2 per cent of quinine.

If the value of the unit is 1d to 1½d, Barks under 2 p. c. would fetch about 1d p. unit.

" " 3 " " " 1½d "

" over 3 " " " 1½d "

The expenses of harvesting, shipping and selling come to about £20 per ton. I will call bark yielding over 3% good, under 3% bad.

I will class producers of ledger bark as No. 1, of different kinds as No. 2, of kinds yielding under 3% as No. 3.

Class No. 1 need not be considered.

Class No. 2 would do well to regard the following.

Crop of 10 tons.	£	Profit.
3 tons 2% at 1d per unit	56	
Less expenses of harvesting, shipping and selling at £20	60	
2 tons 2% at 1½d per unit	58	
Less expenses as above	40	18
5 tons 5% at 1½d per unit	291	
10 tons less expenses as above	100	191
5 tons under 3% destroyed.		
5 tons under 5% (average of good ledger) at 2d per unit	466	
10 tons less expenses as above	100	366

But would the value of the unit stop at 2d supposing the supplies to be reduced by one-third or more?

Class 3 are the chief producers of bad bark, and they have to consider whether (if it pays them at all) it will pay them best to continue, to throw on the market their bad and to depress and keep down prices or to cut down their trees and destroy the bad bark, in which case there would be a probability of prices rising and being really remunerative when the suckers which would spring from the "stools" would be ready and would produce good.

Class 3 should recollect that had barks had their day from 1877 to 1883.

Getting all producers to agree to carry out a plan. This is a point which all bark growers would do well to consider. The chief difficulty is the intense jealousy which seems to be felt if one class obtains a slight advantage over another.

Ceylon contains most of the bad kinds, but planters there are doing well with tea: they would then be the better able to sacrifice their bad bark.

Java has taken the lead in thinking of plans to meet the situation: there is therefore the more probability of their joining in any good plan.

W. T. HOBY.

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F.R.S., F.G.S., &c.,

EDITOR OF "SCIENCE GOSSIP."

The active and industrious French agricultural chemists, Professors Schloesing and Laurent, have just read another important paper before the Paris Academy of Sciences on "The Fixation of Free Nitrogen by Plants." They arrive at the conclusions that there are some inferior green plants capable of fixing atmospheric or gaseous nitrogen. Under the conditions of their experiments they found that peas take up much atmospheric nitrogen, whereas fallow soils, oats, spurrey, mustard, &c., are not capable of fixing it.

Two French chemists, Messrs. Arnaud and Charriu, have been devoting their attention to quite a new side in the natural history of microscopical germs and organisms. They find that the quantity of oxygen absorbed by them is in proportion to the quantity of carbonic acid gas evolved. In a vacuum, evolution of the latter gas takes place slowly. In an atmosphere of pure carbonic acid there is no development of microbes. In hydrogen, on the contrary, there is considerable development, with formation of ammonia. The quantity of nitrogen converted into ammonia by these organisms is sometimes as much as 70 per cent. With asparagine it rises to over 90 per cent. The weight of the microbes and of the productions of their secretions was found to be considerably greater with gelatine than with asparagine.

There are few questions which are more interesting to scientific agriculturists than the life-history and work of the micro-organisms in the soil. It is to them we owe the possibilities of a higher life. The old notion that plants could live on inorganic matter in the soil is not correct. Their plant food has to be prepared for them, and the bacteria prepared it. Mr. Müntz has recently shown that nitrites are only found in soils in very small quantities; whilst on the other hand, when nitrifying organisms are introduced large quantities of nitrites are formed. Dilute solutions of calcium nitrite undergo no change when left in contact with oxygen for months. The simultaneous action of oxygen, or of the ordinary atmosphere and carbonic acid gas, on solutions of calcium nitrite completely converts it into nitrate. Oxygenation takes place when the nitrifying organisms are about. Mr. Müntz is of the opinion that the nitrifying organisms convert the nitrogen into nitrites, and that the latter are converted, without the further action of any organisms, into nitrates by the simultaneous action of the oxygen and carbonic acid always present in soils. On the other hand, some of our best English investigators believe that the work of producing nitrites and nitrates is performed by two distinct species of soil bacteria. It is satisfactory to know that microbes are pretty much like ourselves—their are both good and bad among them.—*Australasian*.

ORANGE RECIPES.

ORANGE FRITTERS.—Make a nice light batter with one-half pound of flour, one-half ounce of butter, half a teaspoonful of salt, two eggs, and sufficient milk to give the proper consistency, which would be about one pint; peel the oranges and divide each into eight pieces without breaking the thin skin; dip each piece into the batter; have ready a pan of boiling lard or clarified dripping; drop the oranges in this and fry a delicate brown—from eight to ten minutes. When done, lay them on a piece of white blotting-paper before the fire to drain away any greasy moisture that may remain, sprinkle them over with white sugar and serve hot.

ORANGE PUDDING.—Take the yolks of three eggs, one tablespoonful of cornflour, one breakfastcupful of powdered white sugar, one pint of milk; make into a custard by allowing it to come to the boil to thicken. Peel and slice five oranges and put the slices into a pudding dish, with sugar sprinkled over each layer. While the custard is quite hot, pour it over the

oranges; make a whip of the whites of three eggs and two tablespoonfuls of sugar, place on the top, and brown very delicately in the oven.

ORANGES IN SYRUP.—Score the oranges all over in imitation of some ornamental design, representing basket-work or trellis-work, and then simmer them in water until nearly done through. They must next be put into cold water for twenty-four hours, changing the water every three hours. At the end of this time they should be drained in a sieve for several hours, then placed in an earthen pan and covered with a hot syrup made by boiling three pounds of sugar and one quart of water for five minutes. For three successive days let the syrup be boiled up and skimmed, and when nearly cold pour back upon the oranges; after the last time the oranges may be put away in jars, and used for dessert when required.

LEMON CUSTARD CHEESECAKES.—Ingredients: One-half pound of puff paste, four ounces of butter, four ounces of powdered white sugar, four lemons, eight eggs, and one drop of essence of lemon. How to use them: Put the butter, sugar, the juice of four lemons, and rubbing of one lemon into a stewpan; add the eggs, then stand the stewpan in a pan of boiling water on the fire, and continue stirring until the ingredients become quite a thick custard; take off the fire and stand in a pan of cold water, and stir until quite cold. Roll the puff paste out the thickness of a quarter of an inch; now cut some round pieces and lay them in tartlet pans, press out the paste from the center with the thumb and finger, then place in each a teaspoonful of the mixture. Then put them on a baking tin, in a moderate oven, and bake a pale brown. When baked take out of the pans and let them get cold, then dish them on lace paper in glass or silver dishes.

PINEAPPLE PUDDING.—Ingredients: One pint of milk, six eggs, six ounces of sugar, six sponge cakes, a tin of preserved pineapple and three ounces of dried cherries. How to use them: Butter well a pudding mould, and ornament the top with dried cherries and pieces of pineapple; put in the sponge cake (broken in pieces) and some more pineapple (broken in small pieces); into a basin put the milk, the sugar, and the eggs, whisk all together until the sugar is dissolved, then add the syrup of the pineapple to it; turn the mixture over the sponge cakes in the mould, cover with buttered paper, and steam one hour and twenty minutes. Chop the rest of the pineapple very fine, turn the pudding into a hot dish, place the pineapple around it and serve immediately.—*Good Housekeeping.*

COFFEE CULTIVATION IN JAVA.

AMSTERDAM, March 9.—Last week the advices of the Java Government upon the report of the States commission regarding the coffee cultivation in Java was received, from which it appears that the Governor-General disapproves the proposals made by the commission as leading to unsatisfactory results. The realisation of the views of the commission would cause a loss of about 3,500,000 guilders, calculated according to the average coffee production during the years 1883-87. Although some of the measures proposed might be useful they would never answer the purpose of replacing the State cultivation by a free native cultivation. The Governor positively states that the system of the commission would be the ruin both of the Government's free cultivation, and, moreover, the financial sacrifice expected in the future are not to be estimated. He can therefore fully agree to the ideas of the Director of Home Government, who has projected a system which will promote alike the interest of the State and that of the people and private industry. This system is based upon the principle of paying wages according to labour and a prudent working of the still available Government grounds, joined to a mode of cultivation which will give back to the soil what has been taken from it. Provisionally His Excellency analyses the maintenance of the Government's cultivation, with the abolition, however, of the injustices and faults connected with it at present. The total abolition of the Government's cultivation is a matter to be considered in the future, when experience will have taught

in which way this ought to take place. Notwithstanding this, the complete freedom from compulsion must be the aim for the promotion of which the system of the Director of Home Government seems to give the best guarantee. This system will be less expensive than other plans, and will further secure the necessary stability in the revenue derived from the Government's cultivation, although no guarantee can be given that the annual production will be in the first years about 700,000 piculs, required to get the equilibrium in the budgets. In this way the ideas advocated during the last forty years will be gradually realised. In connection with the Governor's report the Council of India has advised: the maintenance of the price of 15 guilders per picul of coffee for compulsory cultivation, with a premium of 100 guilders per bow for ordinary, and 150 guilders per bow for compulsory cultivation, according to the regulation projected by the Resident of the Preanger districts. Further, the compulsory cultivation is abolished in those places where it is proved to afford more burdens than advantages to the population, or gives no remunerative results to the Government, in consequence of payment of the premium referred to above. In order to encourage the free coffee cultivation provisional freedom from compulsory labour will be granted to those working new estates out of the "desa's," and further authority will be allowed to construct and maintain roads on Government's account, if the trials to be made in six districts prove successful. An Inspector, with two assistants, should be appointed to carry out this new regulation.—*L. and C. Express, March 11.*

WYNAAD PLANTERS' ASSOCIATION.

From the proceedings of a general meeting held at Meppan reading room on 2nd March 1892, we take the following:—

Office Leaf Disease.—Read proceedings of Madras Government Revenue Department, dated 28th January 1892, No. 587, recording a letter from the Government Botanist, dated 16th January, 1892. No. 10—Extra.

2. "I may here state that I made some hundred and more cultivations of the *Hemilea Vastatrix* when in England, so far back as the year 1873 and that since I came out to India, I have made three separate series of cultivations, but in none of these latter cases have I advanced upon my first ones, or on those made subsequently by Mr. Marshall Ward. I have been constantly on the look out for evidence which might point to the *Hemilea* being innocuous, but I have found none. The *Hemilea* is undoubtedly common to other plants, besides the coffee, so that the abandoning of coffee for a few years would not get rid of the pest. This is suggested by Dr. Cunningham himself in his letter.

3. "I quite agree with Dr. Cunningham in thinking that any further investigation in the life history of the *hemilea* would be valueless to the planter, but it might furnish information which would be of very great interest from a Botanical point of view."

THE ENCOURAGEMENT OF PLANTERS IN PERAK!

(To the Editor of the "Pinang Gazette.")

SIR,—During the eighteen months or so that have elapsed since the question of coffee cultivation in Perak was taken up by the *Pinang Gazette*, I have used my best endeavours to induce planters and capitalists to try their fortunes in that State. Some minor alterations were made in the rules relating to transfer of leases of land and other correlative matters, and the circulars of April and July may be said to have been the outcome of inquiries made direct to the Resident on behalf of Ceylon planters.

Now that matters have been advanced a stage or two, and a few blocks of land selected and surveyed, it has become apparent how very little has been conceded to the would-be planters, and how much more must be done by the Government of Perak before it can be said that it is encouraging capitalists to invest in coffee cultivation. The price at which land

can be bought, \$1 per acre, or the equivalent of R9, is only ten per cent. less than the upset price, at which the Ceylon Government puts up forest land for sale, with all the advantages of a previous survey, and access by rail and road already provided. When the land has been acquired, for a so-called premium, it is not held by a freehold title but is still subject to a number of land regulations which prevent a man from saying "May I not do as I will with mine own," for verily it is not his own but still the property of the State. When representation is made that there is no means of access for prospecting the jungle without the loss of time, and the expense incurred by hiring Malays and taking supplies into the jungle, which is naturally a difficult proceeding for strangers not conversant with the language of the natives or the nature of the country they wish to explore, we are told that eight or ten years ago a number of planters went through the country and examined the jungle from end to end, and at that time there were few or none of the present roads which intersect the State in every direction. In addition to this, we are reminded that the first planters in Ceylon took up their lands under similar conditions. Very true! and see the result. In Perak, the examination of the country, and subsequent concessions of land, in inaccessible regions, was the sum total of what resulted from the visit of most of the planters of that time. The very few who did remain and open coffee estates either abandoned the attempt and went away, or else laid their toms in the country, so that there can hardly be said to be much encouragement held out to men who are now told to go and do likewise. As regards the pioneers in Ceylon, who commenced operations before the era of roads and rails, I apprehend that hardly a single one of them made anything out of the venture, the general smash-up of 1848 being a proof of the assertion. If it is a fact that the Government of Perak is anxious that ten or a dozen men should make a lot of money by way of encouraging others to come in to the country, it is evident that it must do something more than tell them to go and incur the risk and trouble and expense which resulted in the ruin or death of those who have previously made a similar venture. There is at present but one valley of hill forest which will be served by a cart road for a short distance and then by a bridle path, which is under construction. And when, in accordance with directions from the Land Office, and permission granted to take up land "anywhere you like," as long as it has not been already taken up and demarcated by some one, we proceed to select in this valley, we find that other parties have a prior right of selection, and that until they choose to come to some determination on the subject, nobody else can do anything—two years time being the shortest period named for the purpose.

Until measures are taken to enable visitors, in the first place to inspect the elevated jungle land of the State, and in the second place to provide for the transport of supplies and produce when the Estates are opened, there is not much chance of any large extension of the cultivation of coffee *Arabica*. These remarks do not apply to the same extent where we come to Liberian coffee, low lying tracts of country suitable for this variety lying adjacent to many of roads already constructed. In this connection I wish to point out an extraordinary and vexatious regulation affecting land already planted, and more that has been taken up for planting, in the interior districts of the State. At Kuala Kangsar, a sort of custom house has been established, and the coffee grown in the district has to be taken to this customs house and weighed before it is allowed to go on to Taiping, and the privilege (if) of doing this has to be paid for at the rate of two and a half cents a picul. Let us see how this works. At present the only estate giving a crop lying on the Ipoh side of the town, has necessarily to send its produce through the town, so that there is no extra transport incurred; but anposse the estate lay eight or ten miles on the Taiping side, it would, in order to comply with the present regulations, be necessary to send

the coffee 16 or 20 miles out of its way to the port before it is allowed to leave the district. Again, this coffee has to be weighed at Kuala Kangsar to please the Government, weighed a second time at Taiping to please the railway authorities, and finally weighed a third time at Port Weld to please both the Government and the steamer agents. This is, of course, all by way of encouragement to planters! Another difficulty results from the inability of the Land Office to cause the immediate survey of the land taken up. We are told to go and demarcate the land, and in due course the Land Office will proceed to survey it, the cost of the two operations coming to something like one and a half dollar an acre. The whole question of survey in the State appears to be in a muddle—at any rate it appears to be a stranger—and will probably remain so until the whole of the surveys are placed under one head, instead of being as at present divided between the Land Office, the Survey Office and private surveyors, each treading upon the other's heels—and toes too, if credit is to be given to general report. To facilitate the commencement of operations, permission has been given to employ certain private surveyors, whose work, when duly checked and approved, will be accepted by the Government, and this is the only concession obtainable at present.

Clause No. 12 of the General Land Regulations places the planter at a very serious disadvantage indeed. "The right to take, and to authorise others to take timber, charcoal, gums, and all other natural produce from unfiled forest and uncleared land, is reserved by the Government." The planter is thus unable to reserve any timber for building purposes, if he happens to be near a mining village, which may spring up at any moment and he is liable to have at any time Chinese, and natives of all descriptions, wandering about his land and destroying his property without the ability to check them in any way. This is by no means an imaginary possibility. I can point out a block of 500 acres of land selected six months ago, with abundance of fine timber upon it, which in another six months time, at the present rate of exhaustion, will not have a stick worth felling left upon it. At Blanda Mabok there are hundreds of acres of land entirely denuded of forest, which has been used for the mines. Tracts of land taken up for agricultural purposes must be protected from similar loss of timber. On pointing this out to the State Commissioner of Lands, we were told that in clearing the land the planter wastes the timber, for he burns it all up, and it comes to the same thing if the timber is taken away by miners and others. This reply is worse than perille; for, it must be evident that, as clearing the land necessitates the burning of the timber upon it, it becomes all the more important for the planter to preserve for estate purposes all the available timber on the uncleared land. If the Government wants to encourage planters to purchase land, it should hold out as an inducement that the timber, charcoal, gums, atseps &c., &c., should be at their absolute disposal, to sell, or reserve, or make use of as circumstances might dictate. Such a concession would help the planters and be but little appreciable loss to the Government. Another argument freely used in this connection is that the mining interest must be nursed, as it forms the main source of State revenue, and that the cultivation of coffee is an interest of a very indefinite value. Granted; but the Government asserts that it is endeavouring to further the coffee interest in every way it can, and it is very evident that being in its infancy, it requires nursing a great deal more than mining, which is hundreds of years old.

I have made this letter too long already, and will not trespass further on your space. I may never set foot in Perak again, but am convinced that encouragement to coffee planters must take a different form than at present obtains, if any important interest is to be created within a short period of time. An immense deal has been done for Perak in fifteen years, but this is not the time to halt on the road of progress,—asking men to come to the country for a particular purpose, and then apparently grudging them any little concession they may ask for.—Yours faithfully,

EDMUND WOODHOUSE.

Ponang, March 10th.

ON TEA.

The daily papers have of late so frequently discussed tea, that there is not much left to be said on the subject. The rivalry between Indian and Ceylon as against China, and the eclipse of the Chinese as tea growers, have been referred to again and again, and a very good advertisement for Indian and Ceylon teas, has this frequent reference proved. A writer in the *St. James's Gazette*, under the head of "Common Objects of the Household," deals with tea, and if there is nothing absolutely new in his article, there are several points of interest in it. He says:—Every lady who does her own shopping is aware that there is now considerable difficulty in getting China tea pure. Generally she is offered India or Ceylon; and if she asks particularly for China, the shopman can only accommodate her with a "blend." Even in very large establishments where pure China tea is kept, it is not recommended, but sold, as it were, under protest. The enquiring customer, who asks the reason why, is told that China teas are no longer what they were, and that they have been superseded by Indian. There is no doubt about the truth of the latter statement. It is a fact that China, which in 1864 supplied 97 per cent. of our tea, now supplies only 25 per cent. The trade has undergone a complete revolution, particularly in the last eleven years. Some very interesting statistics have been drawn up by Messrs. Gow, Wilson and Stanton, the well-known brokers, which bring out the following facts among others:—(1) From 1866 onwards Indian tea advanced so persistently in favour that in 1888 it took first place with a consumption of 86,000,000 lb., against 80,000,000 lb. of China. (2) Ceylon tea, which was not introduced in any quantity until 1885, progressed even more rapidly, and in its turn beat the Chinese last year. (3) China produce, though it increased a little up to 1879, did so at a much slower rate than Indian, and after that date continually declined, slowly at first, but since the introduction of Ceylon with great rapidity. Thirty years ago it monopolised the market; today it is but a poor third. While our total consumption has doubled, the supply from China has diminished by more than one-half. These are facts which admit of no dispute, but when we come to ask the reason it is not at all easy to get at the root of the matter. Party feeling, if one may use the expression, runs so high in the trade that an unbiased expert opinion is rare. On one side it is said that China teas have deteriorated to such an extent as to be unfit to drink; and the reason why they have deteriorated is that they are still prepared by hand in the ancestral fashion, while the British-grown article is made by machinery. Nothing of the sort, say the Anti-Indians: China teas are still far the best, partly for the very reason that they are made much more carefully by hand; they have been ousted from the market because the others have been so persistently pushed in the retail trade, and because a coarse article suits coarse tastes. Even in a large merchant house, which deals impartially in both, you will find the men in the India-room speaking with scornful contempt of the flat, insipid Chinas; while those in the China-room shrug their shoulders in pity for people who can tolerate the coarse and common Indians. So the battle goes on, and the trade is rent in twain. Let us try in all diffidence to hold the balance.

An impartial observer will at once perceive that, as usual, all the truth cannot be on either side. China teas cannot have deteriorated merely because they are made as they used to be. That is an excellent reason for their being no better, but not for their being worse. And, again, the ascendancy of the others, rising steadily through a series of years, is not to be explained by mere pushing. The public knows very well what it wants, and, though always ready to be won with a new love with highly-painted charms, it returns to the old with the constancy of perfect fickleness the moment it discovers that the charms are painted. No bad thing holds the market long, however pushed; and, beyond question, the teas of India and Ceylon do suit the public taste—which, by the bye, is a very good thing

for British industry. The truth seems to be that China produce has indeed deteriorated, though to nothing like the extent alleged. Only the commoner sorts have been affected. Just like many of our own manufacturers, the Chinese fell to spoiling their magnificent market out of sheer greed. They pillaged their plantations so recklessly that, to keep up the supply, they had to fall back on old leaves and inferior stuff. This partly explains the change, but it is not all. The rival kinds have an advantage which of itself would inevitably bring them to the fore; they are more economical—they possess more strength, body, or whatever you like to call it, and therefore go further. Most people judge their tea in a ready sort of way by colour and strength, according to a private standard. Suppose a lady tries a new kind; she puts in the quantity she is accustomed to, and the drinkers pronounce it too strong or too weak, as the case may be, by their own standard. The quantity is correspondingly diminished or increased, and at the end of a week or month the housekeeper finds herself on the right or the wrong side. Now, India and Ceylon will go half as far again as China; if one pound of the latter makes five gallons, the same quantity of the former will run to seven and a half gallons. The argument is irresistible to the middle classes, and even to the rich; but, oddly enough, less so to the poor. Spending nothing on the outside, they are intensely particular about the inside. In London, for instance, inferior coffee goes west, not east; there what they have must be good. And until lately a certain small dealer among the South Wales miners used to take regularly 100 chests of the finest China tea at a time. Since the strike the good man has gone bankrupt. At the same time the poor, as a rule, like a good twang to their liquor, and so the rarer teas flourish more or less all along the line.

As for the actual merits of the rival kinds, that is, of course, a matter of taste; but no one will deny that for delicacy of flavour China remains unapproached. For that reason it is used for blending throughout the trade. It is altogether a prettier, more refined, more interesting article; epicures will have no other. The difference is much the same as that between Australian and French Burgundy. The one is a capital thing in an ordinary way, and gives you more show for your money, but there is no charm about it. China is the ancestral home of the cultivated plant and the drink, though the wild shrub is indigenous in Assam. The finest kinds—the Clos Vougeots, so to speak—have no counter part in India; but then we never see them here either—they are too dear. Russia takes a good deal, for the Russians do not mind paying high; but the best of all—the superior Oolongs—are consumed at home among the upper ten thousand (or is it ten million?) and they fetch 12s or 15s a pound on the spot. Excellent China tea, however, still comes to London, of as good quality as ever, and very much cheaper. Owing to depression in the trade, samples which would formerly have fetched 2s 8d now go for 1s. But the retailer prefers dealing in Indians, because they are all sold in the open market and the price is known; whereas the China merchant buys privately, and can charge what he likes. That is how he used to make a fortune; but the day is gone; it is the retailer who makes the profit now, and a big one—not less than 6l to 1s a pound. Naturally, he prefers to push the Indian teas, and this has an important bearing on the trade.

We have classed India and Ceylon together because they have the same character on the whole; but there is a difference. Ceylon approaches more to the character of China, and this may account for its remarkable success. Both have unquestionably a great future before them, which is matter for congratulation; for the amount of British capital now embarked in the business in the two countries cannot be less than £40,000,000. Other places where tea is grown are Natal, Fiji, Jamaica, and Johore.

Something should be said about the relative wholesomeness of different teas. On this head it

is more easy than wise to dogmatise. Exact science has really very little to say about the composition and physiological effects of tea; but it may be safely asserted that "strength" implies tannin, and tannin means indigestion. The strong Indian teas should therefore be carefully used and not allowed to brew too long. Properly speaking the infusion should not stand more than five minutes; after that it begins to get bitter, and there is poison in the cup. We Anglo-Saxons always take our tea too strong, and have to smother it with milk and sugar in order to disguise the bitter taste—a practice unknown to the other great tea-drinking races. They take it pure and weak, thereby getting more flavour without any bitterness. The Chinese method of brewing is practically the same as that used in the trade for tasting. Enough leaf to make a cupful—that is, the equivalent in weight of a sixpence—is put in a small bowl and boiling water added; it is then covered over and allowed to stand five minutes, after which the liquor is poured off clear of the leaves into another vessel. Made in this way the drink is at once more agreeable and more wholesome; but the Englishwoman would, of course, rather die than give up the teapot and the cosy. Her tea is never undrinkable from bitterness; she only apologises for its being cold.

Referring to the above article, Mr. John Roger late tea planter in Ceylon, writes:—"As one of the first to open a tea-clearing in Ceylon (in 1880), I naturally read with considerable interest the article on tea which appeared in your issue of the 14th inst. On the whole, I think these references in the *St James's Gazette* to the three great tea-producing countries are characteristically just and impartial; but I believe most people will admit that the ordinary teas, for some time back, sent home from China, have gradually deteriorated so much in quality that they are now poor indeed, and it matters little to the ordinary consumer that it is still possible to get fine teas in China at prohibitive prices. The superiority in the mode of treating the leaf, which our countrymen have adopted in India and Ceylon, was strikingly illustrated the other day by one of the more intelligent Governors of China sending to India and Ceylon for planting experts, to teach his countrymen in China how to make tea with the aid of machinery. I believe the taxes now imposed on native Chinese tea-growers prevent their really cultivating their gardens, which are overrun with weeds. Generally speaking, you would not get one barrowful of weeds off a hundred acres of a Ceylon tea estate. The rapid rise of the tea industry in Ceylon occurred to me the other day when I was sending an advertisement to the papers offering tea-plants for sale here in London reared from seed imported from Ceylon; for I remember advertising in the Ceylon papers for tea-plants twelve years ago, and I could not get them. It is a curious fact that tea-plants are now being sold in London, and are to be seen growing in many shop-windows today, and twelve years ago not one could be got for love or money in Ceylon itself. Twelve years ago the total export from Ceylon was only about one hundred thousands pounds; this year it is about seventy millions. We are undoubtedly getting more and more a tea-drinking people, for seventy million pounds of Ceylon tea represent a much greater number of tea drinkers than the same quantity of China tea would do; and the British public like to feel or taste something for their money. They prefer the teas of India and Ceylon with a 'grip,' and do not want the poorer liquor of the China article. What is tannin? May not the cheering qualities of the cup be ascribed to tannin in a great measure, which may therefore be a good thing when taken in a legitimate way? No one need cry out against tannin who makes tea properly, though the essence or extract of tannin may cause indigestion."—*H. & C. Mail*, March 18.

INDIAN AND CEYLON TEA.

"HONOUR TO WHOM HONOUR IS DUE."

To the Editor of the *Home and Colonial Mail*.

Sir,—At the present time, when so much is being done to make public the merits of Ceylon tea,

and when such success is attending the efforts made by the Ceylon planters to call attention to their wares it appears to me that both the merits of and the important position held by Indian tea are apt to fall into the background.

All honour to the perseverance and push which has characterised the efforts of our neighbours in Ceylon, but they and their advocates should, at any rate, adhere to the truth, and also take the pains to inform themselves a little more carefully and accurately than they appear to do regarding the position held by their chief competitor—India. Such fairness and such fairly looking in the face of facts regarding Indian tea will probably in the long run be not adverse to their best interests. To show to what extent this ostrich-like burying of their heads in the sand may carry those who are interested to magnify the position of Ceylon tea, I call the following from a most interesting ably-written book, lately published by Mr. Walters, entitled "Palms and Pearls." Speaking of the future of tea, he writes:—"It does not, therefore, seem rash to affirm that the tea shrub has found in the island a congenial home, and that Ceylon will take and keep its place as the tea country of the world." And in reference to the possibility of blight attacking the plants he writes:—"But the fact remains that, up to now, tea in Ceylon has been free from the ravaging blights which, in India, often reduce the crop by one-half the average."

Of course, the inference in the minds of those who read these two paragraphs will undoubtedly be that—(1) the great bulk of tea, now consumed, comes from Ceylon, and Ceylon only, whereas, as a matter of fact, taking the season just closed, the proportions of the tea supply reaching this country are roughly, something like:—

India	about 50 per cent.
Ceylon	about 25 per cent.
China	about 25 per cent.
Total.....100	

These figures, of course, are only approximate, and rather overstate the Indian proportion. The actual figures are more like the following:—

India	110,000,000
Ceylon	60,000,000
China	65,000,000
Total 235,000,000	

As regards the blight, of course anyone acquainted with the Indian planting industry knows that the writer's assertion is a gross exaggeration as the utmost extent by which the worst of blights, probably reduces an Indian crop is from 5 to, at the outside, 10 per cent in quantity.

(2) As regards the future, it may be assumed that the increase of output from year to year is, after the close of the present year, not likely to exceed in Ceylon the rate at which it goes on in India, say perhaps about 10 per cent per annum in each case, and it is to be hoped that, by the joint efforts of the two large and powerful planting communities, the increase of consumption will be kept about level with the increase in production.—I am, sir yours, &c., OBSERVER.

London, March 16th, 1892.

THE AMSTERDAM MARKET.

AMSTERDAM, March 22.—All the analyses of the cinchona-bark for sale here on March 31st have been published now. The results are as follows:—The manufacturing bark contains about 14½ tons sulphate of quinine, or 4.68 per cent. on the average. About 6 tons contain 1 to 2.23 tons to 3, 84 tons 3 to 4, 90 tons 4 to 5, 52 tons 5 to 6, 24 tons 6 to 7, 18 tons 7 to 8, 3 tons 8 to 9, 9 tons 10 to 11 per cent. sulphate of quinine.—*Chemist and Druggist*, March 26th.

QUININE AND CINCHONA IN BRITISH INDIA.

In our issue of June 9, 1888, we gave an account of the process for manufacturing sulphate of quinine then newly inaugurated by the Indian Government upon some of their cinchona estates. Further details of this process are now made public in Mr. Lawson's report on the Indian Government cinchona plantations. That report deals with the quinine factory at Naduvatom, in the Nilgiri district. The *modus operandi* followed at Naduvatom is practically the same as that published about two years ago; hence, although the account is repeated in the present report, it does not add, and could not be expected to add, much to our knowledge. Some wrinkles have evidently been gained by experience. The bark is no longer powdered so fine as it was at first, a No. 64 sieve having proved sufficient for the purpose, instead of the No. 130 one first employed. The proportions of cinchona powder, alkali, and kerosene, have also been slightly modified, the present formula being to place 200 lb. of powdered bark in a cylindrical vat with 100 gallons of water holding 14 lb. of caustic soda in solution, adding to this a mixture of 96 gallons paraffin and 24 gallons fusel oil, and agitating for three hours with a revolving paddle. The subsequent process of drawing off the oil into which the alkaloids have been incorporated, dissolving out the latter by means of water acidulated with sulphuric acid, filtering the acid liquor through charcoal, crystallising out the sulphate of quinine, and drying the crystals, is all substantially the same as when described eighteen months ago. The bark now used for manufacturing purposes at Naduvatom is a mixture of branch, stem, and root of *Cinchona officinalis*. It has an alkaloidal value of 3.02 per cent. quinine, 1.01 per cent. cinchonidine, 0.14 per cent. quinidine, 0.24 per cent. cinchonine, and 0.30 per cent. amorphous. Its equivalent in quinine sulphate is 4.06 per cent. The factory has had to struggle with a good many adversities before it was able to work without interruption on a large scale. The manufactory was started at Naduvatom in June, 1889, but it took four months to train the native workmen to their task. This work accomplished, it was found that the loss of the costly fusel oil was so great as seriously to hamper the working of the process, and the manufacture had to be suspended until February, to admit of the erection of a still for recovering the fusel oil. Just as everything was ready to start, influenza broke out at Naduvatom, and all the native workmen ran away to their homes in Mysore, a fresh squad having to be engaged and drilled. Finally, the steam-engine was found inadequate for its work, and the plant had to undergo a thorough alteration. All obstacles, however, were ultimately overcome, and since the end of May of this year the factory is in full working order. The cost of manufacturing the first batch of 227 lb. sulphate of quinine was 3,915.12 rupees, or 17.4 rupees per lb., equal to about 1s. 6d. per oz. It took 6,000 lb. of bark to obtain that quantity of sulphate of quinine. The value of the bark was 3,626 rupees; fuel, chemicals, and the cost of plant amounted to 205 rupees; and for labour only 84 rupees, or less than one-third of a penny per oz. of quinine, is charged. It is, therefore, not likely that the Indian Government quinine will do much injury to the sale of the European article in the East, even if it should ever attempt to enter into serious competition with the latter. But as the Naduvatom factory is only estimated to turn out the comparatively insignificant total of about 65,000 oz. per annum, there is not much chance of that.

Added to Mr. Lawson's report on quinine manufacture is a statement by Mr. D. Hooper on the progress of the Government plantations during the year under review, which contains some interesting notes on the experiments on the artificial increase of the alkaloidal value of cinchonas. Since 1886 a valuable series of experiments on the effect of manuring on the different species of cinchona has been inaugurated, and the result has been to prove that the application of ammoniacal manure, such as

cattle, stable and ponce, to cinchonas is always attended with a profitable outturn of a large quantity of richer bark, especially on young and fast-growing species, as *Succirubras*, *Ledgers*, and *Hybrids*, and that the agents employed act more energetically upon younger trees than older ones and upon the fast-growing trees just mentioned that on the slow-growing *officinalis*. It remained to be proved whether the action of fertilising agents for a longer period on *officinalis* trees would be attended with remunerative results, and what effect they would have upon mossed and renewed barks.

In order to elucidate this problem careful experiments were made with ten *officinalis* trees at Dodabetta. Four of these were eleven-years old trees and six twenty-one-year-old trees. The manures used were bone-meal, fish, lime and cattle manure. One pound of the bone-meal manure or 2½ lb. of fish manure were used to each tree, but the quantity of the other manures employed is not stated. Of the eleven-year-old natural *officinalis* trees, the one manured with bone-meal yielded 5.78 per cent. of total alkaloid and an equivalent of 4.95 per cent. of sulphate of quinine. That manured with fish afforded respectively 6.82 and 5.94 per cent., while from lime and cattle manure 5.68 and 5.19 per cent., and from bone-meal and cattle 5.97 and 5.35 per cent. respectively were obtained. The results obtained from the twenty-one year old trees, were, as follows:—Renewed bark: fish manure, 8.21 per cent. total alkaloid, 8.43 per cent. sulphate of quinine; bone-meal manure, 7.02 per cent. total alkaloid, 7.02 per cent. sulphate of quinine. Mossed bark: fish manure, 6.61 and 5.97 per cent.; bone-meal, 7.48 and 7.02 per cent. respectively. Natural bark: fish-manure 6.14 and 5.54 per cent.; bone-meal, 7.38 and 6.85 per cent. respectively.

All these are exceedingly good barks, when compared with the natural crown bark, containing an average of 3 per cent. of quinine when grown in the same situation without manure. The fish manure especially has raised the amount of quinine to a considerable extent in the barks to which it was applied.

In the present critical state of the cinchona industry such experiments must be of considerable value to planters.—*Chemist and Druggist*.

SUGAR FROM SORGHUM.

(From Bulletin No. 12. of the Louisiana
Sugar Experiment Station.)

The sorghum plant in China is poor in sugar and sensitive to frost. At Rio Grande it has been acclimated so that it will stand quite a severe frost with ice, and been educated to imbibe five times its normal dose of sugar. Such results so deservedly merited from the persistent energy of its intelligent managers, is exceedingly gratifying especially when it is remembered that State bounty was withdrawn two years ago.

Encouraged by the prospects of diffusion extracting all the sugar from cane, the citizens of Ottawa, Kansas, led on by Hon. W. L. Parkerson, established at that point a few years since a large and complete factory. It is merely necessary to say here that it failed, after the promise of great success.

Convinced that only a few more persistent and intelligent efforts were needed to wrest from sorghum the sugar which it contained this same Mr. Parkerson, repaired to Fort Scott, and there erected the Parkerson Sugar Works, whose name and fame are now written and spoken in every tongue. With national aid, liberally bestowed, with scientific skill bending its energies upon one single accomplishment, with improved machinery erected for a sole purpose, the Parkerson Sugar Works of Fort Scott, Kansas, sounded its determined attack upon sorghum early in the fall of '86, and millions of souls awaited the issue with intense solicitude.

The interest deepened as time wore on, and the dailies with intelligent correspondents at the seat of war, were denounced for withholding the news from

Fort Scott. Foreign countries had sent ambassadors to investigate and report upon this strange plant which under the influence of diffusion was to revolutionize the sugar world, add the name of Fort Scott to the commercial sugar marts upon the blackboards of sugar exchanges, and make all Kansas rich and happy. It is a pity to say failure to all these high hopes and bright anticipations, but the truthful chronicler of history has so recorded, and the chemist in charge has officially announced "the absolute failure of the experiments to demonstrate the commercial practicability of manufacturing sorghum sugar" which fell upon our intelligent Commissioner of Agriculture "like a wet blanket," to say nothing of the chagrin and grief, amounting to almost discouragement which followed.

"Human fortitudo is equal to human calamity" was one of the impressive sentences contained in the "farewell address" of Lee to his army at Appomattox, and its truth has been fully verified in the history of the Parkerson Sugar Works. Undaunted by failure, and urged to renewed exertions by the unjust attacks of carping critics, the courageous managers calmly surveyed the field of disaster, reviewed the causes as far as known, and calmly resolved upon another trial. Defective and superfluous machinery was removed, uncertain or useless processes were eliminated, pet theories were abandoned and simplicity and pure science left to conduct a campaign, which has attained a success that finally places sorghum sugar making among the profitable industries of this country. The success of '87 at Fort Scott is due 1st, to the almost complete extraction of the sugars from the cane by diffusion. 2nd. The prompt and proper treatment of the juice in defecating and evaporating. 3rd. The efficient manner in which the sugar was boiled to grain in the strike pan.

According to the report of General Manager Parkerson, the cost of labour and fuel per ton of cleaned cane was \$1. The estimated cost of salaries, wear and tear of machinery etc., another dollar, making a total of two dollars per ton for manufacture. Upon this basis with the same yield of cane and product secured this year, it requires but little figuring to show that we have developed a business of great interest and profit to our State and nation," is the conclusion of Mr. Parkerson.

The total cane worked into sugar 2,643 tons; the total sugar made 285,826 lb.; or per ton of cane worked 89.2 lb.

No second sugars were made—
 The sugar sold for 5½ cents and netted .. \$13,559 98
 The State bounty was 2 cents per pound 4,716 52

Total 17,276 50
 There were also 51,000 gallons (estimated)
 molasses at 20 cents 10,200 00
 Seed valued at 7,900 00

Value of total product \$34,476 50

EXPENSES.

Paid for cane and seed \$ 9,614 00
 Labor 5,737 16
 Fuel 1,395 77
 Salaries 3,500 00
 Insurance, etc 1,500 00

Total expenses \$21,746 00
 Total value \$34,476 50
 Total expenses 21,246 93
 Net \$13,229 57

Had the factory been in the South, and made the same yields, the account would have been different in the following: No State bounty; an increase of cost of fuel, and a probable decrease in the price of molasses.

There is however one feature of the above account which it is hard to realize:

The cane with seed cost \$9,614 00
 The seed is valued at 7,000 00
 Making 2,643 tons cane cost only \$2,614, or not quite \$1 per ton.

The financial success of the above, while highly gratifying to the manager, is not apparent upon

close examination. The molasses and seed remain, and are estimated at \$17,000.

Since the company, as we learn, has closed its works for the coming season, it is fair to presume that some of its stockholders do not regard the enterprise as profitable. However, the problem of making sugar from sorghum is solved, and the question is now only a commercial one.

THE CLOVE CROP.

In a circular recently issued by a well known Rotterdam firm of spice dealers appears the following regarding the outlook for cloves:—

"Zanzibar reports, under date February 2 last, state that the total crop this season is by far the largest on record, and is estimated at 800,000 frazileh, or about the double yield of former abundant crops. A frazileh is equal to 35 lb., and the total yield, therefore, will be about 28,000,000 lb., while the average requirements of the whole world are estimated at only just over 11,000,000 lb. Prior to 1871 the price of fair Zanzibar cloves in London averaged from 3½d to 3¾d per lb., and although since then an export duty of 15 per cent. of the value has been established, the difference between the prices mentioned and the actual quotation of, say, 4¾d to 4½d is much larger. The large yield is undoubtedly a consequence of the replanting which has been going on in Zanzibar after the hurricane in 1872, the trees having now attained their full growth. The fact that the trees bears fruit every second year only leads to the supposition that the next crop will be a small one, but it is said that a much larger number of trees has been planted since the hurricane than ever existed before. At any rate, the current crop is much in excess of the requirements, and concurrently with this exceptional Zanzibar crop the yield of cloves in the island of Amboina (Netherlands Indies), though of much less importance commercially than Zanzibar, has also been greatly in excess of the average." In reply to these alarming statements, it is said, according to the *Chemist and Druggist*, that no European house can possibly have any means of correctly estimating the crop of Zanzibar cloves, as the bulk of this article is produced on the small island of Pemba, north of Zanzibar, which is entirely in the hands of the natives, who do not allow any foreign traders to obtain accurate news of the crop; but the estimate given by the Dutch firm is thought to be much exaggerated.—*Oil, Paint and Drug Reporter.*

THE OUTLOOK FOR INDIAN AND CEYLON TEA PLANTERS.

TO THE EDITOR OF THE "HOME AND COLONIAL MAIL."

Sir,—Indian and Ceylon planters are undoubtedly coming face to face with and every day drawing nearer to a crisis in the history of the tea industry, unless they take steps, which I believe they can, to prevent it.

When we consider there is certainly not less than £20,000,000 of British capital sunk in tea property, the subject, from its magnitude alone, is deserving of more than a passing attention.

I would first desire to explain how I arrive at this immense sum of twenty millions sterling.

India and Ceylon last year produced in round figures 180 million lb. of tea, and the average yield per acre may be taken at 360 lb. We thus have an area of 500,000 acres under tea, and the average cost of tea estates in India and Ceylon may be taken at £40 per acre, the result being a capital outlay of twenty millions sterling.

This sum does not include the outlay on railways, roads, and public works constructed for the purpose of serving this enterprise, which must amount to a few millions more.

Year after year there has been a steady fall in the price of tea, and 1891 resulted in a gross price of 10d. per lb. being realised for the teas of India and Ceylon.

The difference in price of teas from each country was merely fractional, and need not be considered.

The great and serious difference between the two countries, apart from that of quality, is in the cost of production. I gathered from the excellent table of figures of twenty-seven Indian tea companies, published by Mr. Henry Esraebaw, that the cost of production for India tea is 9d. per lb., and from other reliable sources that Ceylon lays its teas in London at a cost of 6½d per lb.

Now, what do these figures mean? They show that India, on its 1891 crop of 109 million lb., made a profit of about £454,000, while Ceylon, on its crop of 68 millions, made a profit of £990,000.

Should the price of tea, therefore, fall another 1d per lb., Indian planters would cease to earn a profit, while the Ceylon tea planting industry would be profiting to the extent of 2½d per lb. on, say, 80 million lb. of tea, equal to £817,000 per annum.

If we carry the argument still further, we shall find that, if the price of tea reached the low limit of 6¼d per lb. (and the Indian properties remained under cultivation) they would be suffering a loss of over £1,600,000 per annum when Ceylon found itself in the position of simply paying expenses.

I do not say that the price of tea will recede to this extent, but I do not believe prices have yet touched bottom, and will not, I think, do so until a halt is made in the expansion of the production of British-grown teas. In about three years' time India and Ceylon will be exporting 25 per cent. more tea than they did in the past year. New markets develop slowly, and consumption will probably be unable to keep pace with this extra supply, unless very strenuous efforts are made to push the teas into consumption in new fields.

Ceylon has certainly done her share nobly in this respect, and it behoves her bigger sister, India, to move forward in the lead thus given her.

It requires no great foresight to predict what will happen when prices recede further, and that India will be the first to suffer from her lethargy in not having pushed her teas earlier into new markets.

Although Ceylon all round will make a profit should the price of tea go down another twopence per lb., there will be a considerable acreage, however, giving small yields and prices below the average, that will be worked at a loss.

In India, again, the majority of properties will be suffering heavy losses.

Planters, however, will no doubt continue to cultivate, hoping for better days, and will be slow to abandon even non-paying properties.

The poorer fields will cease first of all to be cultivated; and on estates where this course does not stop the loss, a point will soon be reached when the unfortunate proprietor or company can hold out no longer, and the garden will become abandoned.

The low prices will have the immediate effect of preventing new lands being opened out for planting, so that in the course of a few years, when certain areas are thrown out of cultivation, we shall probably not only have no increase, but possibly a decrease, in the output of British-grown teas.

When this time has been reached, the new markets will be making themselves felt, and consumption will have overtaken supply, so that the position will from that period gradually strengthen, and good profits will be made by those proprietors who have been able to tide over the few bad years.

The land thrown out of cultivation when unproductive of profit will gradually be reopened, as tea bushes, unlike coffee, are not killed by neglect, and may possibly improve by allowing them to follow a natural state of existence for a few years.

There are many gardens in India which doubtless produce tea as cheaply as those in Ceylon. I, however, am not dealing with individual properties, for, in discussing this subject, the average results from each country can only enter into the comparison. From what I have stated, it would appear that Ceylon holds an eminently strong position, which will enable it to engage, without fear, in the struggle for the survival of the fittest.

If it be true that the English nation and Australian Colonies will not again go back to the common grades of China tea, even if they could be had pence per lb. under the price of British-grown teas, then the tea planters of India and Ceylon may look with unconcern on the future. It will not do, however, for them to listlessly look on and allow the tea trade to drift until it settles down *somehow*. If they hope to stave off bad times, I would venture to suggest the following advice:—1. To absolutely cease planting up more land with tea. 2. To endeavour to keep a good standard of quality, and not be tempted, when prices improve, to sacrifice quality for quantity. 3. To maintain, with liberal funds, their organisation for pushing teas into new markets. 4. To effect economies, if possible, in the cost of production.

I have faith in Ceylon planters working shoulder to shoulder, as they have so often done before, when they see clearly that a united effort and a strong pull all together will bring them through their dangers; but the absence of cohesion among Indian planters, I fear, will only accentuate the possibility of their drifting into asperilous position.

The tea enterprise in both countries is (taken as a whole) sound, but as critical times, although only temporary, seem to be in store, more specially for India, it might be well for the leading companies, proprietors, or planting associations to collectively endeavour to see how best they may mitigate, if not altogether avert, what might otherwise prove to be a situation of no inconsiderable gravity.—Yours, &c.

SCRUTATOR.

London, March 15th.

THE GIBBS DRYING MACHINE

is thus noticed in *The Sugar Cane*:—

This machinery, which is adopted for all manufactures in which the products are required to be dried, and which for several years has been adopted in London and in Australia, Java, and other countries for the drying of sugar and megass, has recently undergone improvements in its application to tea-drying. The Gibbs Patent Puro Hot Air Furnace, after many experiments, has proved a perfect success in supplying the means of obtaining either from coal or wood, or both, a hot air so pure that it can be inhaled without injury or inconvenience, and is therefore suitable for application to the most delicately flavoured tea, coffee, &c., or other produce without possibility of taint. It is now not only possible but easy and economical to obtain the utmost amount of heat from coal without any deleterious accompaniments. It may interest our readers to learn that most favourable reports have been received from various parts of India and from Natal.

The latest use to which the Patent Drying Cylinders (see advertisement columns) have been successfully adapted is that of coffee drying.

Some months ago Messrs. Gibbs sent out one of their Dryers to a large house in Rio de Janeiro, Brazil, and by the last mail from this country they have been advised that at a public trial held the machine gave great satisfaction, the opinion being that it is the best of the many dryers in the market.

The apparatus in question consists of a horizontal rotating cylinder 36 ft. long by 3 ft. 6 in. diameter, through the centre of which at one end a circular tube or air-duct projects some 12 feet; this tube is open at one end, and connected with a fan, which draws a supply of heated air from a specially constructed furnace, capable of burning wood, coal, or other fuel.

The opposite end of the air-duct is fitted with a perforated iron plate through which the heated air-currents are distributed into the cylinder.

Both ends of the cylinder are partially closed with wire mesh discs, which, while retaining the coffee, allow free escape for any vapour.

In the shell of the cylinder are a series of apertures or ports covered by slides.

The modus operandi is briefly as follows:—

The cylinder is first placed upon a slight incli-

nation (a sliding bracket being provided at one end whereby the inclination can be easily adjusted), so that the coffee fed in at the higher end gradually travels down to the opposite or lower end, where it is retained by the wire mesh disc above mentioned.

When the cylinder has been thus fully charged it is set down level and kept continually revolving until the charge is dried, the slides covering the ports in the shell of the cylinder are then drawn out and the coffee rapidly discharged, by again placing the cylinder upon an incline.

It should have been mentioned that the interior of the cylinder is fitted with shelves or lifters, by which the coffee is distributed in a constant shower over the whole area of the cylinder, through which the heated air-currents are passing.

The machine effects an enormous saving in labour, turns very little fuel, is easily erected and worked, and the whole mechanism being extremely simple there is no liability to get out of order, and it is only reasonable to expect that a Dryer possessing such advantages will prove exceedingly popular.

NOTES ON PRODUCE AND FINANCE.

THE OUTLOOK FOR TEA PLANTERS.—In our correspondence columns will be found an important letter upon the position of the tea industry in India and Ceylon. It is written with the authority of one who knows his subject, and on this point we can assure our readers. The letter may give rise to some controversy, but whether this be so or not it claims attention, and should help to stir up members of the tea industry to the necessity for continuous action in the search for new markets. It is clear that Ceylon planters have taken the lead so far as new markets are concerned, and they have been altogether more on the alert than their Indian *confrères*. The energy and vigilance of the Ceylon planters have been incessant, and no opportunity has been lost for advertising Ceylon teas whenever a chance offered, as witness the protest of another correspondent, who calls attention to the exaggerated statements made in a recent hook on Ceylon. There has been much said hitherto as to the friendly rivalry between India and Ceylon, but this friendly rivalry has a serious difficulty to face. The common enemy, China, has been vanquished, and now the cry is that tea production has overtaken the consumption, and unless unity of purpose be resolved on, it will be a case of the "devil take the hindmost." It is imperative that new markets should be found. Our correspondent "Scrutator" believes the position serious, and one requiring immediate attention. He advocates more cohesion and the display of some collective wisdom in facing a situation of such gravity.

TRAVANCORE PLANTERS' ASSOCIATION IN LONDON.—An association, under the above title, has been formed in connection with the Travancore Planters' Association, and has, among other things, for its objects:—To watch and protect in London the interests of tea, coffee, and cinchona planters, and to advise the parent association of all matters affecting these industries. All residents in the United Kingdom interested in Travancore are invited to become members of the association. The parent association subscription is £10 10s. yearly, and the annual subscription for members in this country has been fixed at £1 1s.—Arrangements have been made with the Ceylon Association in London for the use of their rooms at 4, Mincing Lane, where members can meet and peruse papers bearing on the objects of the association. The president of the association is Mr. Patrick Grant. Subscriptions may be forwarded to the hon. secretary, Mr. Ewen Cattanaich, 3, Great St. Helens, E.C.

A TALK ABOUT TEA.—The managing director of the National Wholesale Tea Supply Association (Mr. Slaney) gave the young grocers' assistants of Manchester some advice about tea a few nights since. There was, we are told, an exhibition of a collection of specimens, curiosities, &c., which Mr. Slaney had been able to obtain through the kindness of many of the leading tea brokers in London. One

specimen of tea, valued at from £50 to £60 per lb., the produce of an Indian estate, gained special attention. Mr. Slaney gave his audience some very good advice, as well as a description of the teas supplying the English market, first dealing with the products of our colonies India and Ceylon, and then with those of China and other countries. In giving some hints on obtaining a knowledge of tea, Mr. Slaney said: "In no branch of business does the axiom that 'knowledge is power' apply with more force than in a knowledge of tea. The opportunities of the grocers' assistants of today, speaking generally, are somewhat meagre, and it is difficult in many cases to get to know anything about this article. The only course is to make best use of the opportunities you have, not to remain satisfied with them, but to endeavour to extend them wherever practicable. Those who are favourably placed with an intelligent employer who studies tea and keeps a variety of stock, and can obtain access to the testing and blending-rooms, have opportunity of picking up knowledge."

THE TASTE OF THE CONSUMERS.—Referring to the consumers' taste in tea, and the efforts the grocer should make to meet it, Mr. Slaney said:—"Amongst the working-class population, generally speaking, tea with strength is preferred to fine tea of high quality and less strength. A cup of tea made from a rasping, pungent Indian pekoe souchong and thick, strong broken pekoe would be appreciated, where a cup made from a choice Darjeeling tea, costing four times the money, would not please. Many dealers pay great regard to the weight or bulk of a tea, preferring heavy close leaf, because, I suppose, users get more weight into their teaspoons when measuring into the teapot; hence tea-mills are used to reduce the size of some of the excellent liquoring teas, whose only fault is their possessing a large or ugly leaf. The steel roller operates and licks it into shape, enabling the users to blend these descriptions to advantage along with other teas at a higher cost, because, after all, the appearance has something to do with regulating the price or value."

SOUND ADVICE.—"Never deal in tea," Mr. Slaney added, "that is objectionable in flavour, or that you would hesitate to drink yourself. Avoid earthy, minty, sour, or coarse teas, or teas which, owing to the scarcity of wood in the districts in which they are grown, are packed in wood from Japan having a cedar or drug-like odour, which is soon conveyed from the chest to the tea. Avoid by all means keeping or storing tea in proximity to any strong-smelling articles, such as soap, cheese, oranges, apples, &c. Keep tea in a dry, warm room, where it will improve. Let your blended tea be prepared a time before sale. A fresh blend, made up from identically the same teas and in the same proportions as one blended a fortnight before, will not taste near so well as the older one, whose flavours have assimilated by the teas lying together. Let your customers see that in pushing the sale of tea your aim is to please them, not to effect just one sale and no more, and if you are assured that the goods you handle are equal to the best of any of your competitors, whoever they be, success will be likely to attend your efforts. I might take up more time by going into the subject, 'How to match blends.' This is a higher branch, and, like analysis in chemistry, requires deep study. One hint here may be useful. Adopt the narrowing down process, and come to an accurate conclusion of the kinds or varieties that you suppose are not present; then, having fewer kinds to deal with, you more readily judge the constituents of the sample under notice. In a case of this kind observe the appearance in dry leaf and infused leaf—the leaf infusion under treatment of varying time, say five, seven, or ten minutes, spreading out the leaf on white paper and judging by complexion of leaves. Testing the liquor against both originals of the teas you suppose to predominate, and blends you consider similar, will, with constant practice, enable you to perform both the analytical and synthetical processes required when you wish to match or follow any particular blend.

A NEW INZA.—A description recently appeared

in the *Echo* of certain Tee To Tum clubs formed in the poorer neighbourhoods of London, in which teetotal principles and practice were to be inculcated and bars for the sale of tea a leading feature. Mr. P. R. Buchanan's name was mentioned in connection with the scheme, and, according to the *Echo*, he was "able to raise the necessary capital from among his friends." The idea of these clubs, or at least Mr. Buchanan's connection with the experiment, does not commend itself to the grocery trade, if we may accept the views of the *Grocer's Chronicle*. In an article entitled "Philanthropy in the Tea Trade," the writer says:—"Certainly no one can object to the establishment of comfortable clubs for those whose homes are, to say the least of it, very unattractive, but grocers have a perfect right to object to having their legitimate business taken away from them by clubs, whose proper business is to supply refreshments, but who are going outside their province when they take up the work of retail distribution. If Mr. Buchanan is really a disinterested philanthropist, he ought to take care, whilst doing good to the poor, that he does not increase their number by undermining the business of honest tradesmen."

LAST WEEK'S TEA MARKETS.—There is still a pleasure to sell the low and common qualities of Indian (says the *Grocer*), which form the bulk of the existing supply, and these have been disposable only at easy and irregular rates, as the trade are too full of stock to bestow much attention upon them, and the presence of these teas constantly on offer gives the market a flat and drooping aspect, that can be relieved only by an immediate and prolonged curtailment of supplies. The quality of Ceylon has reached a poor average during the past week, and this feature is a serious drawback to the trade. Growers would profit well by sending forward better teas, also by reducing the number of breaks. Small breaks are generally sold at low rates, as many buyers do not trouble about tasting them.—*H. and C. Mail*, March 18.

TEA IN MOROCCO.

When a party of guests enters the house or the tent of a rich Moor, one of the near relatives of the host is charged with the duty of making tea. He equips in one corner, having on either side of him a large server or platter. Upon one of these servers are a number of cups and upon the other a sugar bowl, a box of tea, a pile of fragrant menthe leaves, a copper apparatus for heating water and a tea urn. The tea-maker sets the water to boiling with a little fuel, and then pours the boiling water into his tea urn, quickly adding to it some tea and some sugar, and allows the compound to steep a few moments. Then he pours out a cup of tea and tastes it, smacks his lips, sniffs the odor of the liquid and draws a deep breath—all with an air which says: "I am going to get this tea just right." The chances are that he does not find the compound to his taste at the first attempt, for he pours the tea in his cup back into the tea urn, adds a little sugar or a little tea, and pours out another cup for a second test. This process goes on, the tea-maker tasting his tea and pouring it back again until he gets it to his mind. Then the guests are called, and if any one of them does not finish his cup he is expected to pour it back into the urn, for it is the custom in Morocco to take three cups in succession, and the tea-making has to be begun over again.—*American Grocer*, Feb. 24.

IN A TROPICAL FOREST.*

BY ALLAN ERIC.

It may not be generally known that the cinchona plantations of the island of Jamaica, in the West India, yield bark far superior to the best grown in Ceylon. It is commonly supposed that the Peruvian bark tree in America grows most readily only on the slopes of the Andes, between the equator and ten degrees of north latitude and twenty degrees south

latitude. This was once correct; but in the island of Jamaica, several years ago, Peruvian bark trees were found growing on the slopes of the Cooca Cura mountains, and while not plentiful, the bark was found to be of excellent quality. As both the climate and soil of the mountain slopes in America were found to exactly suit the Peruvian bark tree, the people, encouraged by the wealthy planters and rich merchants on the coast, have been propagating it, and have planted, within the last ten or fifteen years, large plantations of cinchona, which are now producing bark which is taking a leading place in the markets of the world. Such a plantation I had the pleasure of visiting while on the island a few months since. The Peruvian bark tree, to begin with, belongs to the natural order *Cinchonaceæ*, which yields the bark so much valued in medicine, and otherwise known as Jesuit's bark, quina, quinquina, cinchona, chibchona, etc.; and from which the important alkaloids *quina* or *quinine*, *cinchonine* or *cinchonidine* are obtained. I have seen these trees while riding over the mountain paths in Jamaica, scattered among growths of cocoa, cabbage-palm and pimento, fustic and logwood; but it is most usually found near some spot practically clear of other trees. Some of the cinchona trees are very large; but the best bark comes from small ones, which appear as shrubs after the large trees are felled. It must be remembered that cinchona exist in many varieties, chiefly distinguishable by the different localities in which they grow, but whose quality is essentially and to all practical purposes the same. They are all ever-green trees. They very closely resemble laurels, and the shrubs still more closely resemble the "lamb-kill" of the New England pasture. The cinchona has entire opposite leaves, stipules which soon fall off, and panicles of flowers, which very closely resemble lilac blossoms. The flowers are white, rose-coloured, or purplish, and very fragrant; and I now have some of the flowers, which were given me by a native named Brava, and which I pressed in my notebook which I carried in my saddle-bag while riding through the Jamaica mountains; and even now, pressed and dried, they retain much of their fragrance. The calyx of the flower is small and five-toothed, and the capsule splits from the base upward. This is the true cinchona. There is another of a similar species which I have seen growing in some localities in the tropics; but I noticed that in this, the subgenus *Casarella*, the capsule splits from the top downward. The two look very much alike, but the latter has no commercial value and no trace of the valuable alkaloids is to be found in it. The cutting and peeling of the cinchona trees are carried on by the natives in the dry season. The trees are felled as near the roots as possible, that none of the bark may be lost and the bark being stripped off, is carefully dried, the quilled form of the inner bark being acquired in drying. The bark is made up into packages of various sizes, but averaging 150 pounds in weight, closely wrapped in woollen cloth and afterward in hides, and conveyed to the points of shipment on the coast, on the backs of mules and burros. These packages are called seroons, or drums.

The soap tree, *Sapindus saponaria*, is another tree that I frequently met with during my journey into the interior; and I frequently saw the native women stripped to the waist, standing in the swift-running mountain streams washing their scanty clothing, and using the pulp of the soap berry in lieu of the manufactured article; and I am told that so great is the alkaline property of these berries that they are capable of cleansing as much linen as sixty times their weight in soap. The berries each contain, embedded in the pulp, a shining and very hard black seed. The soap tree is found principally growing at the bases of the mountain ranges, being hardly met with at a higher elevation than 3000 feet above sea level.

Before me I have a large glass jar of alcohol, containing a branch from the anatto, or anatto tree, which I gathered at Mt. Diabolo while the black driver of the Royal Mail stage-coach was changing his mules. It has reddish, oblong, hairy capsules about two inches in length, and from the dried

* From the *New England Druggist*, February.

samples in a box near by I find that each capsule contains about forty seeds. The leaves are boat-shaped and pointed, and the blossoms, which my specimen does not show, are large and of a peach-blossom colour, and grow in loose clusters at the ends of the branches. Those, for such the motto tree really is, rarely exceeds eight or ten feet in height. The tree is very pretty when the capsules are ripe, the vivid red colour of the clusters of pods or capsules contrasting very beautifully with the rich, dark green leaves. The colour of my preserved specimens has changed somewhat, being now nearer a chocolate brown. The seeds are gathered from the pods, put in in bags and exported in large quantities from Jamaica. In some cases the natives obtain the anatto pure by rubbing off the pulpy pellicle which covers the seed. In this case the pulp is pressed into square cakes and wrapped in the leaves of the tree itself.

While at St. Ann's Bay, my host, Mr. A. D. Jacobs, took me out and showed me, piled up near the water's edge, several cords of logs each about eight inches in thickness and about four feet long. "That," said Mr. Jacobs, "is quassia wood." This tree, known in the West Indies as *Pierona*, quassia being the name given to it by the Maroons, grows almost everywhere in Jamaica principally quite near the coast, so cutting it and transporting it to points of shipment are comparatively easy. It is a very lofty tree, and very beautiful as well. This is the species from which the quassia cups and quassia chips, so well known to us, are obtained. Growing up at a higher altitude, and at some distance from the coast, I found another species of quassia. This one is known to botanists as *Sinaruba*. It is a shrub ten or fifteen feet high, and bears beautiful bright red flowers. This wood is very bitter and very much stronger than the other; and being scarcer, at a greater distance from the coast, and superior as a drug, it has a greater commercial value.—*Pharmaceutical Journal*, March 19.

TAMIL COOLIE LABOUR.

TO THE EDITOR OF THE "STRAITS TIMES."

Sir,—As a probable employer of a very large force of Tamil or K'ling labour over here in the near future, I trust you will allow me space to record a protest against the action of the Madras Government in placing, as it does, every impediment in the way of planters importing free Tamil labour into the Straits and in saddling this Colony with a burden, in the shape of the exciting Indian Immigration Ordinance, the undoubted working of which cripples extended agricultural operations here. The whole question is one which I am aware has been thoroughly threshed out and dealt with by far abler pens than mine, so, without attempting to criticise the Ordinance at any length, I shall merely endeavour, by a statement of what I myself have seen of its working, demonstrate how nearly akin to actual slavery is the condition of the unfortunate Tamil coolie who is despatched over here under the wing of the over-paternal Madras Government as compared to that of his "free" brother. It is my firm belief if this wonderfully rich Peninsula is to become one of the first if not the very first only office producing countries of the world, it can only be with the assistance and cheerful co-operation of the Tamil coolie. Easily contented, capable of getting through an enormous amount of honest work, quiet, and amenable to discipline and, above, all a confirmed settler,* I doubt very much if there is a better all-round agricultural labourer in the world than the Tamil coolie. But this little word must be spelt with a big B, he is gifted with a very keen and nice appreciation of Justice. You may be hard on him but if you are at the same time fair, he will even take it in good part when, having been unwittingly unjust to him, you make

* Surely, this is only partially true? More have settled in Mauritius than is desirable; and a good many are settling in Trinidad. But in places so near home as Ceylon and the Straits, only a small proportion settle?—Ep T. A.

reparation; but he will do nothing for you if you are consistently unjust, and this I unhesitatingly assert a man is bound to be if, amongst his coolies are any Statute Immigrants, or, in other words, natives of India brought over under the protection of Government.

For an adult male the minimum rate of wages in the case of an indentured coolie is fixed by the I. O. Ordinance at 14 cents a day for the 1st year and 16 cents for 2nd year; for a woman 10 cents and 12 cents. Free labourers or coolies who have come over independent of Government and of contracts made by the Indian Immigration Agent, are paid on estates up to 25 cents a day for men and women up to 20 cents. Consequently, the ridiculous anomaly of a coolie working alongside of another man in no way his superior as a worker, on little more than half the other's pay is a matter of everyday occurrence. Can anything be more unjust than this? and I ask would any labourer in the world work under conditions such as these; and more than this, if the unfortunate wretch refuses to work, he can be sentenced at the instance of his employer to 3 months imprisonment, because he contracted, before he ever came to the country, when he was little more than a savage with the vaguest ideas of what was before him, to work for at least 3 years on about half what he could have got, without bidding himself down in any way, had he been only a little wiser and not quite so wild when he was first caught! The natural question which any one reading the above will ask is "why then not pay the Statute Immigrant the same wages as the free labourer and so equalise matters?" Because the contract in the case of the former is entered into through the Immigration Agent, before the planter sees the coolie with whom he is contracting, and before he can judge of his capabilities as a worker, and also because the large majority of Statute Immigrants are not only worth 25 cents, but also are worth absolutely nothing at all. As an instance of this, a somewhat extreme instance I will allow I knew of a case when a woman with no less than 3 children and no husband or breadwinning friend, was sent over under a 3 years agreement on a daily wage of 10 cents, out of which she had not only to keep herself and her children, but pay off her debt as well; the result was she very soon realized that she had undertaken to do what was quite impossible, collapsed altogether, and was eventually shipped back to India at the expense of the estate the Manager writing off the whole of what he had cost him as "Loss by Coast Advances." Now, if the Immigration Agent had explained fully to her the nature of the contract upon which she was entering, as he is supposed to do, he must have known she was quite unfit to carry out her engagement and should not have allowed her to come over here; if he did not do so why did he not. He is paid to do this amongst other things, and cannot be exonerated from blame whichever way you look at it.

Now as a set off against his meagre wages, the Statute Immigrant is entitled to sufficient house accommodation, good water, proper sanitary arrangements, advances of food at wholesale market prices, hospital accommodation, medical attendance and medicines when he requires them; but here again he is no better off than his "free" brother, who gets all of these things, too, except hospital accommodation, and when he is ill enough to require this, he is sent to the Public Hospital. Now look at the other side of the picture; a planter, were he allowed to recruit his own labour, would send a reliable agent to India who would be responsible for the money with which he would be entrusted as coast advances and also for the physique of his recruits, each of whom on arrival here would be debited with his share of the cost of bringing the gang over &c. Paid 25 cts. a day, he would if he were a good man, save from \$4 to \$5 a month, very soon liquidate his debt, and then be in a position to remit money to the "coast" in sums calculated to tempt all his friends to follow his example. But planters can't do this as the sum of money entrusted to the agent might often be a large one, and as the latter runs considerable risk

of being imprisoned for crimping, in India, to start off with; whilst over here it is the duty of the Immigration Agent to board steamers and explain to Immigrants that they are quite free and under no sort of obligation to anybody unless they have signed contracts of service before some duly authorised Government official. The risk is too great to be run, the influx of labour is stopped, and the extension of agricultural operations is grievously retarded. With the prospect of a rice famine in India and consequently of a large surplus population, and with such an El Dorado for Tawiti as the Straits might easily become, close at hand, the attitude of the Madras Government in this connection cannot sufficiently be deplored.—I am Sir, yours faithfully,

E. V. CAREY.

I have heard it stated that the minimum rate of wages, was fixed as quoted previously, in order to suit sugar planters of Province Wellesley who are said to state that, were their coolies to be paid at the same rates as the free labourers on coffee estates and Government works, they would be ruined. The question seems to me to resolve itself therefore into this, either the agricultural development of the Malay Peninsula must be retarded, or free immigration must not only be sanctioned but supported by Government at the risk of Province Wellesley being ruined, the latter course I venture to think will be of the greatest ultimate benefit to the country, as if the sugar industry is being worked with such a very narrow margin for profit, the sooner others interested in agriculture have some say in the matter the better.—*Straits Times*, March 23rd.

FROM THE METROPOLIS.

March 18th, 1892.

PERU AS A FIELD FOR COFFEE AND CACAO PLANTERS : CINCHONA AND MR. CLEMENTS MARKHAM, C.B., F.R.S.

It will make the mouths of old Ceylon coffee planters water to read all about the virgin forests, rich soil of inexhaustible fertility, fine climate and indigenous coffee bearing up to 10 cwt. an acre, in the Commissioners' Report on Peru when it appears. It will be out shortly; but meantime the 28th is fixed for Mr. Ross's "paper," giving an account of the trip, before the Royal Geographic Society; while on last Tuesday night we had a gathering at the Society of Arts to listen to a paper on "Peru: its commerce and resources" by F. A. Pezet, Peruvian Consul-General in London. Sir H. Trueman-Wood sent me tickets, and I was glad I attended. You will see the full text of the paper and of the discussion that followed in the Society's weekly journal and will no doubt be taking over all of the same that bears on tropical agriculture for the *Observer* and *Tropical Agriculturist*. Mr. Pezet, a bright, young, educated Peruvian gentleman, speaking English well, but reading very rapidly, afforded a great deal of information in his hour; and he had for his chairman a personage so interesting to us as Mr. Clements K. Markham, C.B., F.R.S. Arriving a few minutes late, I quite supposed for half the time that the chairman was again the Attorney-General Sir Richard Webster, so great is the resemblance between them—both are clean-shaven, refined, healthy-looking gentlemen, past middle life with a look of geniality and benevolence almost Pickwickian. Mr. Markham, however, soon revealed his personality, by standing up to point out on a splendid map of Peru, the places, mountains, rivers, districts, &c. as referred to by Mr. Pezet.

SIR ALFRED DENT led off the discussion in an interesting speech, showing how much the enterprising Peruvian Corporation was doing to develop the country by railway extension, placing steamers on Lake Titicaca, encouraging immigration and how they looked, as the result of the recent Commission, for the development of an

extensive industry on coffee, cocoa, tea. ["Not tea," whispered in Ex-Ceylon planter beside me—"protest!"] Sir Alfred Dent also alluded to the great value from a commercial point of view of young Englishmen learning Spanish, which was of more value to a merchant than even German.

COLONEL HARRIS, a white-haired veteran who had spent 25 years in Peru, followed with extremely interesting particulars and more especially dwelling on the rich deposits of gold as yet untouched, mentioning on scientific authority that there were many streams the sands and waters of which, at certain points, would yield very handsome returns.

To him succeeded COLONEL CHURCH, a true grizzled Yankee and great traveller all over South America, who amidst much that was historical and flattering told some plain truths as to the Peruvians having been demoralized in the past, cutting each other's throats in revolution after revolution, everybody living on "guano" from the Government downwards, and doing no work, and then turning to the Nitrate fields which, however, as the result of an unjust war were wrenched from Peru by Chili. A regular blessing this, in disguise; for ever since the Peruvian community had begun to work, develop, and prosper in the true sense. But as regards immigration, Colonel Church had to say that better laws and better treatments must be given to strangers before there would be a rush.

Mr. ALEX. ROSS came next in some well-chosen sentences referring to the recent explorations, the delightful climate of Lima ranging in temperature between 60° and 80° as extremes, while he and Mr. Sinclair lived as in England in all save the superfluousness of an umbrella! Mr. Ross spoke highly of the progress making in railway extension, of the several routes travelled, of the many products available, the fine soil and forest land generally.

Mr. J. FRERGUSON followed. I said that I rose because of one word that had dropped from Sir Alfred Dent in connection with the future of Peru, namely "tea." But before dealing with it, I would mention for the information of the lecturer and other of his countrymen and friends present, that the name of "Peru" was familiar in the Far East of India and Ceylon as well as in England and was closely connected with one of the greatest blessings ever brought to the millions of Southern Asia, in cinchona. It was in 1861, the same year as I first saw Ceylon, that their chairman arrived with a few plants of Peruvian cinchona at Bombay—half being sent to the Nilgiris and half to the hills of Ceylon; but no planter, while coffee was prosperous, would look at a "medicine plant," and so recently as 1869 only 20 ounces of bark were exported. But when coffee failed, cinchona was planted and Ceylon ran up to a maximum cultivation of 54,000 acres and a maximum export of nearly 16 million lb. of bark, bringing down the price of quinine from 16s to 20s an ounce to (last year) 1s or 9d [Mr. T. J. LAWRENCE:—Less than 9d] per ounce in Mincing Lano. This was an inestimable boon to millions in India and elsewhere and one with which the names of Peru and Markham would ever be associated; but it proved destructive to the Ceylon cinchona planter; and he had to plant tea instead; and now we were fast becoming a premier tea-growing country, exporting 68 million lb. last year with the prospect ere long of reaching 100 millions, while India was also going on. Now, I would warn planters opening in Peru, to profit by our lesson in cinchona and beware of tea. But,

there were other and very valuable products of which the world's supply just now was really less than the demand, for which Peru was evidently most admirably fitted, notably for coffee and cacao; and I was quite sure that when the Ceylon and Indian planters read the Report (shortly to appear, of my friends Messrs. Ross and Sinclair who had learned planting in Ceylon—the best school in the world for tropical agriculturist—before I reached the island, that the interest of many of them would be awakened, in respect of coffee especially. For coffee in Ceylon and India has failed and is failing, as also to a great extent in Java, and even in Brazil the top of the tide seems to have been reached, while there was evidently a great field for this product and others equally profitable in Peru. I could not but look forward, therefore, with great interest to the financing and development of planting operations in the wide, rich forestlands along the Peruvian tributaries of the Amazon.

Both Mr. Ross and myself were well received.

Mr. WATTS, a practical Wiltshire farmer who had been in Peru, came next with most valuable testimony to the great value of live stock in that country.

The meeting concluded with an interesting speech from Mr. MARKHAM proposing and conveying the thanks of the meeting to the lecturer. He mentioned that Mr. Pezet's grandfather was one of the foremost patriots of his day and indeed fell a martyr to the freedom of his country.

I had the pleasure afterwards of being introduced to Mr. Markham, with some pleasant talk during which I ventured to urge that he should use his official influence to make known the great value of cheap quinine for use among the millions of China, especially among those who were enslaved to, or being, or beginning to acquire the taste for, opium. He agreed that something had to be done in this direction, though gradually the use of quinine was being extended through the Treaty Ports in China.

In this connection I have to mention that Mr. Ross has been elected an Honorary Member of the Royal Geographical Society of Lima.

CINCHONA CULTURE IN ECUADOR.

I had an enquiry from the Colonial Office the other day for information respecting "Cinchona in Ceylon," made on behalf of the President of Ecuador, I referred the authorities to our publications—the "Cinchona Planters' Manual," "Handbook and Directory" and *Tropical Agriculturist*; but chancing to lay my hands on one of my "Agricultural Reviews" reprinted from the Handbook of 1888, I added to it the latest statistical information and sent it on as the best means of at once showing the Ecuador President the foolishness of attempting the cultivation of cinchona at the present time. In acknowledgment of the little book, I have the following:—

Downing Street, March 7th, 1892.

SIR,—I am directed by Lord Knutsford to thank you for the copy of your "Review of the Planting and Agricultural Industries of Ceylon" which you have been so good as to send to this office with the figures relating to cinchona planting corrected to date.

The book has been sent to the Foreign Office for transmission to the President of Ecuador, who has expressed a wish to receive any reports or statistics bearing on the subject.—I am, sir, your obedient servant,

EDWARD FAIRFIELD.

John Ferguson, Esq.

QUININE-MAKING IN ECUADOR.—In South America, according to a French report, the first step has been taken towards the manufacture of quinine on the spot. M. Manuel Jijon has set up a factory at Quito, which supplies the whole of Ecuador, and has begun to export a product which has a very good appearance. The sulphuric acid necessary is manufactured on the spot from native sulphur.—*Chemist and Druggist*.

AGRICULTURAL ADVANCEMENT IN LOWER PERAK.—AN ACRE OF JUNOLE WORTH \$250 IN THREE YEARS.—We hear that an acre of land in Teluk Anson was sold the other day for \$250 hard cash. This land was allotted by the Perak Government to an Indian immigrant brought over at Government expense, and was all jungle three years ago. The man arrived in Perak penniless; he is now worth \$250, less the amount he repaid to Government as advances. This is another instance of the result of the care and energy displayed by the Lower Perak authorities in the matter of agricultural advancement, and is a proof that Indians as agriculturists will do well if looked after. We also learn that about 1,300 acres of land, in the same district, have recently been taken up by Chinese and Malaya for padi planting, and that operations on them will shortly commence.—*Pinang Gazette*, March 25.

SPEAKING at an Agricultural College in England the other day, the Rev. Canon Bagot made some interesting remarks upon the subject of milk. He said that he was a specimen of a man who had been brought up on skim milk. He never tasted a drop of pure milk from the time he was one year old until he was fifteen. It was skim milk for breakfast, for dinner, and for supper, along with oatmeal porridge, and potatoes, and, sometimes a bit of meat. Skim milk was more suitable for infants than whole milk because it contained less fat. Yet in London hundreds of gallons of skim milk were daily poured into the sewers because people would not buy it. A factory had, however been started for making lactite, a substance resembling ivory, from skim milk. The water was expelled from the milk, and the solid matter was first compressed and then turned in a lathe into various shapes. The numerous dairies that are being started all over India, and notably in Bombay as the result of the travelling Dairy Exhibition that visited this country a year ago, might take the hint if they have difficulty in disposing of their separated milk.—*Indian Agriculturist*.

THE TEA DISTRICTS OF CACHAR AND ASSAM are not favourable for railway construction. Sir Bradford Leslie, in his paper on Indian Bridges, remarks:—

Further to the eastward are the fertile districts of Assam and Cachar, which for many years to come must be served from the railway system of the rest of India by the great Brahmapootra river. With the hills in close proximity on either side, and with a very heavy rainfall, the rivers of those districts are numerous and formidable; the plains are covered with a network of creeks and water-courses, which make it a very amphibious sort of country in the rainy season. Should it become necessary in the future to carry land communications across the Ganges or Brahmapootra rivers in Lower Bengal, the question will arise whether tunnelling may not be cheaper than bridging. In the case of a tunnel, a great portion, if not the whole length, would have to be made through permeable strata. Any permanent structure for crossing these rivers involves the necessity for fixing and controlling its course at the site of the structure. Although not impossible, this might prove a costly undertaking, and it therefore seems probable that the present system of working the railway traffic across the lower reaches of the Ganges and the Brahmapootra by ferries must continue.—*Indian Engineer*.

SOME THOUGHTS ABOUT TEA.

When the Lanreate sang
 "Better fifty years of Europe, than a cycle of Cathay,"
 we do not suppose he had in view China's great
 gift to Europe and the world, Thy or Tea,

"which cheers but not inebriates,"

as another poet sang in a poem rising from the every-day pleasure of home to the sublilities of the Millennial glory. Blessings on the man, though he had his eyes askew and wore a pigtail, who first invented tea—the dried and fragrant leaf! His name, if it could be discovered, even if it was a comical aggregation of monosyllabic exclamations such as "Ho!" and "Fu!" and "Fi!", ought to be emblazoned amongst those of the foremost benefactors of the world. There can be no doubt that the tea plant is indigenous to Assam and Burma; and the probabilities are that it found its way into China from India *via* Burma instead of the reverse process which some have imagined. Be that as it may, the roasted tea of China is as superior to the pickled leaves of Burma, as the finest golden tip pekoe excels the coarsest brick tea. The curious phenomenon is that the genius which discovered the preparation of the fragrant leaf by simple and rude appliances should, in all the centuries, have advanced no further. To this day the processes of preparation are stereotyped; and John Chinaman rejects and destroys improved appliances when introduced to his notice. The "better fifty years of Europe" principle is illustrated by the progress made in the labour-saving and quality-improving machinery and appliances which have been invented in the half century since the British have commenced to cultivate and prepare tea, whether pure China, as at first, or Assam indigenous or high class hybrid as latterly; and now, what would the Chinese who first roasted tea on bambu sieves over open charcoal fires—the leaves having been prepared by the pressure of the human hand and perhaps by the imposition of human feet—what would this Chinese inventor, who knew nothing of advanced engineering and patents, say, were he permitted to "revisit the glimpse of the moon" and see at work in the insignificant island of Ceylon, those great triumphs of human skill applied to the preparation of the leaf he loved so wisely and so well, the roller which is such an improvement on the human hand, the draught sirocco and the perfection in simplicity of the Britannia drier! These thoughts on tea and tea machinery on the literature and the science which have brought their votive offerings to shrines which men name tea factories, in the last half century or less, have been suggested by a glance at the latest edition of Rutherford's encyclopedic "Ceylon Tea Planter's Note Book." It contains "all about tea" and a great deal more. Much about wood and coal and petroleum, as sources of heat and force; about iron and timber as structural substances and material for tea boxes; about lead and solder and shingles and nails; about tea tasting and weighing and measurement, and freights and cost and profits; about rupee-cents and pence and sterling and exchange. About the proportion of dry tea to green and withered leaf; about the cost and capabilities of labour, labour advances and the labour laws; with the number of bushes per acre at varying distances, and the profits per acre at varying rates per pound of tea. Even the forester can come to learn with the planter,—fuel being literally a burning question with both,—what indigenous trees to plant at low levels and which of the exotics are best suited for high altitudes: while weights per cubic foot and prices of the local timbers, of cement, lime, bricks, tiles and other building materials with the cost of various descriptions of building,

are given. Much valuable and important literature on tea, originating in India and Ceylon, is extant and can be consulted with advantage; but this, the selected tit-bits and boiled down essence of all, is indispensable even at the price, about which we have heard some murmurs. But surely a book is worth paying for (especially with the rupee so low in value) which tells a man how to open an estate and how to turn its produce to the best advantage, which gives tea exports since they became appreciable in our commerce and the latest dividends of Indian and Ceylon Tea Companies. A reward might well be offered to the man who looks and fails to find in this Planter's Note Book anything, however, remotely, connected with tea. Then comes the curious coincidence, that, although Englishmen have doubtless done their part, the author of the most generally useful and comprehensive book on tea and the greatest and most successful tea machinery engineers are Scotchmen! There is no more mistake about Mr. Rutherford than there can be about Messrs Reid and Loudoun Shand or our good friend and everybody's good friend "Logie Elphinstone." Then we might as well deny the existence of "Aberdeen awa" and the influence its sons have had on Ceylon estate culture and Ceylon estate English ("Wha's mammy's yon?") as doubt that Mr. Jackson of "Rapid roller" and "Britannia drier" fame is a Scotchman, whose model rooms and laboratory are within hail of Balmoral, although his honest and solid machines are made by the Marshalls on the wrong side of the border. We imagined the old-world Chinese sage who invented tea and there stopped, as amazed if he saw the modern automatic machinery applied to the preparation of the fragrant leaf. But surely his ghostly pigtail would stand on end if he heard Mr. Jackson coolly talk of generating electricity as a motive power for such machinery. But no doubt some Milesian will claim Sirocco Davidson as a countryman. Helives and works, brain and hands, to good purpose at Belfast, and we suppose he was born in that North of Ireland city, "because ho happened to be there at the time." But Mr. Davidson, like thousands of other Irish-Scotch, is essentially Scotch, although the purity of his doric accent is somewhat tainted with a tinge of brogue. If a Scotchman does not cease to be a Scotchman because ho emigrates, does his son cease to be a Scotchman because of the accident of his being born in the country to which his parents had moved? Time does not admit of our pursuing this problem or our thoughts about tea further on the present occasion.—Before closing we may add that the Note Book is not faultless. There are some curious misprints for which of course Mr. Rutherford, away in London, is not responsible. One of the most curious is the substitution of Devon as an Indian Tea District, instead of "the Docors," in association with Darjiling and the Terai. But there are spots (at present one larger than our globe) on the sun's face; but the usefulness of the light-giving orb remains. We may add that Mr. Rutherford's useful compendium is published at the office of the "Times of Ceylon."

AN EX-CYLON PLANTER IN AUSTRALIA.

New South Wales, March 6th.

The question of Federation is very far off when we consider the two burning topics in these Colonies, viz.:

(1) Sir Sam. Griffith's wish to encourage kanakas and the New South Wales hatred to the very idea of black labour.

(2) The proposed Stock Tax to be put on all stock imported into Victoria.

At the late discussion on Federation in the Sydney Parliament, no one seemed really anxious for its speedy arrival. The fact is Federation means a smoothing over of intercolonial jealousies, forgiving the past, and altogether starting a sort of ideal Millennium, hand in hand, offering the cheek to the smiter, and one's coat to the robber. But that is not real solemn Federation that was brought about in the United States by the hard cement of bloodshed. It is a stern fact that Federation will never come until all Australasia is roused to a common sense of danger in the panic of a common calamity; as in England, the Unionists, the Irish Party, the Conservatives, though all in antagonism, will all combine against a common foe. But here, there being no outside foe, save the British money-lender; the individual colonies are all taken up with intercolonial jealousies, Victoria says that Queensland and New South Wales shall not flood the country with cattle and horses. New South Wales, on one side, sneers at Victoria's protective precautions and schemes; and, on the other, objects to Queensland employing black labour. She also wants to claim the whole of the Murray. South Australia objects to Victorian unemployed labourers flooding her labour market; while poor Western Australia is struggling to maintain its dignity as an independent colony. I have already written to you about "Kanakas" and black labour for Queensland. This stock tax deserves mention.

At a late meeting the farmers and graziers have insisted in leaning themselves in favour of the imposition of a tax of £2 per head on all imported cattle, 2s or 3s per head on all sheep, and £4 on all horses. The go-ahead Victorians, who are a match for the other colonies in the 'outness and push, not content with being the only colony which insisted Protection, are now going farther; and the graziers and farmers want to benefit too. Great herds of cattle and mobs of sheep and horses have been pouring in from New South Wales, but Queensland especially. The goat runs in the north pour their huge wild cattle, fattened on the way, into Victoria, and the farmers and graziers find that breeding cattle and horses and also sheep, does not pay at all; so they are going to keep out imported stock by heavy taxes, and thus raise the price of food. But now the butcher comes in, and other interested parties, who say "Let 's have the *ad valorem* duty (that is duty according to value); others say, "No, let 's have it by weight and welgh on the American weigh-bridge system." But the majority says: "Rather *value*; look at all the valuating experts required to distinguish between 'store cattle,' and 'fat cattle' and also other *weight*; look at the expenso, time, and trouble in weighing up huge herds of wild Queenslanders." Thus they are going to the general election.

No, that "National Calamity" must come and reduce all to a common level of mutual protection, and not "Protection" against each other. "In union there is strength." You have heard that remark before, I dare say.

My experience of station life continues. My hands healed all right in time, and I am more comfortable when sitting down. The wild careering on a fiery "mustang" champing the bit and flecking its flanks with the foaming spume from its mouth. The Crimean shirt, and neckerchief loosely tied, broad palm-leaf hat, huge spurs, and dread stockwhip. The bearded tanned face and stern voice full of strange oaths, the campfire, the "billy," the "jumper," the blackfellow. No, that is not the real picture. Ordinary English dress, not ever riding breeches. Quiet ambling along fenced paddocks or a perfectly broken trained station horse that almost knows how to open a "gate" or cut out some rams. Deep thought, anxious thought frowning the brow, as the rider slowly ambles along under a fierce sun. No wonder he is silent and grim. Rabbits; tanks drying up; and sheep and cattle getting "bogged" in the still, soft mud; foot-rot; market affected by Melbourne depression; absence of rain; bush fires; cost of rabbit-proof fencing round the run; and so

on;—then a rousing up and a smart canter to leave *atra cura* a little way behind. Now we will see a number of graceful emus moving rapidly thore the timber with a peculiar indulating body fixed on long stretching legs; now we see a number of those ridiculous kangaroos who always excite my derision. They "loap" away. The Scotch word for leap is more suggestive. After a little we draw rein among a fine lot of cattle who stare at us with bright honest but not altogether pleased eyes; or perhaps we may find ourselves in a bead of horses who are decidedly more inquisitive and demonstrative and make advances literally and figuratively. Then out of the timber with the *cool waters* (?) of a mirage! Then back to the comfort of the station, where cool drinks, and bunches of delicious grapes, and a cold shower-bath, refresh and brighten the dusty sunburnt ridor.

Rabbits are truly a curse. I have been wandering on foot with my gun; and though told that they are not worthy of powder and shot, and though I fully intend to shoot ducks or teal, yet, the noblushing effrontery of the rabbit actually washing its complacent mouth with its paws or peeping calmly out of a burrow, or waiting at the entrance of a burrow till the very last possible moment. —I say though I did not intend to waste ammunition, yet I was wroth like old Noah (no it was Jonah who was angry with the creeper). Stop—Why is Jonah like the manager of a Ceylon Tea Estate? Give it up? Well, because—hal! ha! *he was angry with the creeper!* You can see that I made this up, by the context, as the padres say. To return to our sheep. I found a ram among the ewes one day, but that was not all. I found eight ewes among the rams. That was very wrong and forbidden, but still though naughty it was nice and natural. It's the way all over the world. When all the romance and gilt wears off what do you find station life to be? The gentleman-apprentice or "jackeroo" works with the men, wire fencing, post-hole digging, or any job going. He gets what the men got, a pound a week, and his "tucker," but that is only when he has picked up some experience and has his hands in a proper "horny" condition. He is called "Mister," and is respected by the men, if he does not pitch to (*anglice* yarn with) the men, and get familiar and exchange stories and jokes. He may ride out with one of the han's with a small bee like a "quintanny" over his shoulder and dig up "burrs" (plants obnoxious to a wool grower on account of the burrs) in the heat from 7 to 12. This "knocks the crasses out," as you will helieve. Some youths pay £200 a year to do this, and gain "colonial experience." In a big station there will be a number of "jackeroos," who live in the barracks and call at the "house" on Sundays. The station hands' motto is "Go day, come day, God bring Sunday." Sunday is a day of rest to man and beast. The men wash their shirts and moleskins, or read up newspaper arrears, or visit the township for a "droppy," or to have a "pitch" (yarn). Only the Chinaman works. It is enough to give one fever to watch this man. He is of course the gardener. He begins at daybreak, and leaves off with a sigh of regret at night, when it goes too dark. I have an idea he splits firewood for the pumping engine at night. He swears in English at the township boys who come for mulberries and figs. These boys are as wild as kangaroos, and provoke poor "Paddy." Then he swears in Chinese at the fowls who are always getting in somewhere through the fence, and then, working all the time, he begins to sing. I rise and go away, and the slumbering possum almost drops from its branch, and the wild ducks flap noisily up the creek. It is far worse than Mark Twain's gondolier; but it comes from a happy heart. Solomon had not studied the ant sufficiently, and took things for granted, when he told the sluggard to "go to the ant." Why, some ants have slaves, and others hire sweet white bugs from which they suck nectar, and get quite lazy and stupid. Solomon should have said: "Go to the Ohlman, thou sluggard." The Australian workman is down on the Chinaman on account of his cheap industry, but I have dis-

covered another reason he is jealous. White women like Burmese women, find John Chinaman very kind and good to them. Many a trampled hulled wretch finds a haven of rest among Chinamen. Missionaries jump to the conclusion that a white woman married to or kept by a Chinaman is lost and abandoned. I say no. They are happier with the thrifty, kind, muscular, happy Chinaman than with the drunken, brutal, heaving bully of a white man. The terrible pictures of white women in Chinese "hells" is all "gammon." The white man's "hell" is a far more terrible reality for women of that class. Little Burke Street is disgraced more by the larrikin than by the Chinaman. A poor girl bullied by the larrikin's fles for shelter to the Chinese and is well treated. The half-caste Chinaman is a bad bargain, inheriting the evil propensities of both parents.

ABERDONENSIAS.

FIRE RISK ON CEYLON TEA ESTATES.

We have received the following correspondence:—
Ceylon Association in London, 4, Mincing Lane,
London, E. C.,

March 9th, 1892.

A. B. Bagnold, Esq., Secretary, Fire Office's Committee.

Sir,—This Association, as representing the Ceylon tea planters' interests, desires to bring to your notice the excessively high tariff charged by fire insurance companies on Ceylon tea factories, leaf withering sheds, bungalows, and other estate buildings. Those rates vary from 7s 6d per cent. to 40s per cent. This tariff was agreed to by the various fire insurance agents at a meeting held in Colombo on Aug. 30th, 1889.

From figures furnished by some of the leading tea companies, representing forty-seven factories (which may be taken as sufficient data for the whole of the factories insured), we find that the maximum policy for any estate amounts to £5,000 and the minimum £150. These forty-seven estates pay on policies amounting to £88,629 the sum of £795 net for premiums, or 17s 10d per cent. There are some 350 tea factories in Ceylon, the value of which, at £1,900 per estate, amounts to £665,000, giving, at 17s 10d, say £6,000 per annum in premiums. These premiums would therefore allow a liberal margin for charges and profit if two factories were burnt down per annum. With regard to the risk of fires we have no exact figures, but we believe £5,000 would more than cover the losses suffered by fire insurance companies during the past ten years.

The association is of opinion that these high rates have been charged because the real risks are as imperfectly understood by English fire insurance companies as Ceylon life risks were until recently by life offices.

The business has not probably been sufficiently large when divided among many offices to warrant the expense of sending a qualified supervisor to Ceylon to study factory risks, and factory proprietors feel that the tariff has been arbitrarily fixed so excessively high on an assumed heavy risk which does not exist, and the real value of which has probably never been calculated.

This association trusts that the various fire companies will, on consideration, be able to very materially reduce their tariff so as to be more in conformity with the rates paid on the same class of buildings in England, as we are assured that many of the larger tea companies and factory proprietors are seriously considering the desirability of mutually protecting themselves against fire risks rather than continue to pay what they consider the unwarrantable high rates now charged.—I am, sir, yours faithfully,

(Signed) WM. MARTIN LEAKE, Secretary.

(REPLY.)

Fire Office's Committee (Foreign),

63, Watling Street, and 11, Queen Street,

London, March 11, 1892.

Wm. Martin Leake, Esq., Secretary, Ceylon Association in London

Dear Sir,—In reply to your letter of the 9th inst., in which you call attention to what you consider the

high rates charged for tea factories, &c., in Ceylon. I beg to inform you that the matter is not one with which it falls within our province to deal, as the tariff to which you refer has not been settled through this Committee.—Yours faithfully,

(Signed) ALX. B. BAGNOLD, Secretary.

—H. and C. Mail, March 25th.

RUBBER GATHERING ON THE AMAZON.

At the instigation of the editor of the *India Rubber World*, the Department of State, through the consular offices, has been engaged in making some extended researches into the rubber industry of the world. These reports are valuable and interesting, and great praise is due Mr. Hawthorn Hill, the editor of our contemporary, for the effort put forth to secure these reports, by which "the extent of rubber forests of the world has been demonstrated to be so extensive that any possibility of cornering the crude rubber supply is impracticable; that the once-threatened extinction of the rubber forests is apt now to be checked by Governmental precautions against wasteful methods of gathering rubber, and that new sources of gutta percha supplies have been discovered which will prevent a scarcity of this commodity, and thus encourage the building of ocean cables." From these reports we quote the following interesting description of

RUBBER-GATHERING IN THE AMAZON VALLEY.

"The rubber-gatherer rolls out of his hammock as soon as it is light in the morning, takes his gup of rum and his calabash of coffee, starts out to visit his rubber trees. He wears a short pair of breeches, and sometimes a shirt. He goes barefoot, for he must wade through the swamp mud and ooze of the tide up to his knees, and often up to his waist in water. He takes a basket full of earthenware gill cups, a hunk of adhesive clay and a little narrow-bladed hatchet.

"If he adopts the most approved method of tapping the trees, he reaches as high as he can with his hatchet, making an incision in the bark, but not reaching through to the wood. The milk immediately begins to issue in rapid drops or little streams. With a spat of the adhesive clay he immediately fastens one of his little gill cups just below the bleeding gash, and molds the clay so as to make all the rubber milk flow into the cup. Three such gashes, at equal distances around the tree, and at an equal height, is the rule. The next day he will make three more gashes in the same way, just a little below these, three, and so continue, until by the end of the season he will have reached the level of the ground. Each of his 100 or 150 trees is treated in the same way, and he returns home after having travelled from three to five miles, barefoot and almost naked, through thorny thickets and malarial-stomping swamps.

"When he reaches his hut again he takes another gup from the demijohn, snatches a breakfast of salt fish and mandioca meal, which are often moldy from the reeking damp of the swamp, and then starts out again with his calabash hockets to gather the milk, which by this time has ceased to flow. His gill cups are full, or nearly so, and when he reaches home he has milk enough to make four kilos of rubber, on an average. The next task is the coagulation of this milk. For this purpose he has a jug-shaped furnace, made of earthenware, called a *boiao*, open at bottom and top, and with a small aperture at the side to admit the air for the combustion. In this piece of furniture he builds a fire, or rather a smudge, with the nuts of the *inaja* or *urucy* palm. The dense black smoke which rolls from the open top of the *boiao* is the reagent which coagulates the milk. For this purpose the rubber gatherer has a circular-bladed paddle, like the paddle of a canoe, which he smears over with clay so that the rubber will not adhere to it. This is suspended by means of a cord from the limb of a tree just above the smudge. The milk is poured over the blade of the paddle, which is then turned over and round about in the smoke, and in a few moments the film of rubber is coagulated. The same process is repeated of wetting with milk and smoking the growing lump until it reaches the weight of from five to twenty-five kilos or more. Then it is slipped off from the paddle as a mitten is pulled off

from one's hand. This ball is the crude rubber of commerce. If the coagulating has been carefully done it is 'fine' rubber; if carelessly done, and the ball on being cut open at the exporting warehouse shows signs of poorly-coagulated milk or slight mixtures of foreign substances, such as mandioca meal, it is classified as 'middling fine' (*entrefina*). There is also a coarser grade still, called *sernamby*, the native Indian word for 'shells.' This grade is composed of the scraps and bits that have dried without coagulation proper, especially the linings that form in the little earthenware cups and in the calabashes and buckets used in handling the milk, as also the drippings that run down the trees from accidental wounds. These are all rolled up together in a mass and would bring as good a price as the middling fine, were it not for the leaves and other rubbish that manage 'innocently' to stow themselves away in the lump.

"In future issues we hope to be able to find room for further notice of these reports, giving statistics of amount produced, value, etc."—*American Grocer*, Feb. 24th.

ZANZIBAR AND THE CLOVE TRADE.

At the time of the publication of the last annual statement of the trade of the United Kingdom with foreign countries we pointed out that in no direction had our foreign trade grown more largely during the last five years than with the countries of which Zanzibar is the chief business centre. Our imports from those parts were worth 129,227*l.* in 1886, in 1890 they had grown to 722,803*l.*, while the exports, in the same period, advanced from 254,421*l.* to 521,190*l.* Since the publication of those figures a new British political officer, Mr. Portal, has been sent to Zanzibar and has assumed practically the government of that island. The city has been declared a free port, and sundry other reforms have been initiated which will no doubt contribute largely to its commercial importance. Mr. Portal has just sent home his first report on the commerce of our new dependency, in which he expresses himself full of hope for the future. A big cloud, however, obscures the commercial sky of Zanzibar at this moment—viz., the over-production of cloves, its staple article of trade. Since the clove-tree was first introduced in the islands, about sixty years ago, it has been an enormous source of wealth to the Arab landowners and to the Sultan. There have been periodical depressions in the price before, but until about three years ago 6*s.* to 7*d.* per lb. was considered a very low quotation, and once, after a hurricane which destroyed the greater part of the plantations, the value of cloves rose to 1*s.* 7*d.* per lb. in the London market. Lately, however, the clove crops have become larger and larger, and they are now almost every season greatly in excess of the world's estimated annual consumption, which is about 80,000 bales of 140 lb. each. As a result the price (3*d.* per lb.) has fallen to within measurable distance of the lowest point it has ever touched—viz., 2*d.* per lb., in 1860—when, however, there was no export duty, or at any rate a much smaller one than at present.

The London warehouses are burdened, at this moment, with a stock of not less than 34,000 bales of the spice, and the quantities warehoused in America and on the Continent are also known to be exceedingly heavy. The cause of the present depreciation of cloves lies exclusively in the short-sighted policy of the Arab plantation-owners in the islands of Pemba and Zanzibar, who have neglected the culture of all other products which they might have reared with profit upon their fertile soil, and turned every available acre of land into a clove-plantation, without the least thought of the inevitable effect of their action. The people and the ruler of Zanzibar have for years been practically dependent upon the returns of the clove-crop for their sustenance, and the problems that confront Mr. Portal, in consequence of the breakdown of the one remunerative industry of the island, may, in proportion, become as difficult a solution as the situation created by an Indian famine or a failure of the Nile flood in Egypt. Telegraphic information received this week states that the Arab landowners have presented petitions to Mr. Portal declaring that they are ruined by

the low price of cloves and the scarcity of labour, and asking for a reduction of the clove tax. There is no doubt that, sooner or later, these demands, so far as the reduction of the export duty is concerned, will have to be granted. The puzzle will be where to find a source of revenue which will recoup the Sultan, to whom Mr. Portal stands in the relation of a kind of *maître de palais*, for the loss of the mainspring of his income. Cloves are the cork by which the Court of Zanzibar is kept afloat. "A few years ago," says Mr. Portal, "the price of cloves used to range from \$7 to \$10 per *frasila* (35 lb.), and the export duty taken on them by the Sultan was 30 per cent *ad val.* The price does not now exceed \$2½ to \$2¾ per *frasila*, and the export duty has been reduced to 25 per cent." The 25 per cent. duty, the growers probably think would give them a fair margin of profit; but there is no doubt that if it were abolished tomorrow, it is not the Zanzibar Arabs, but the European spice-dealers and oil-distillers, who would profit, for quotations here would certainly answer with a corresponding fall. The scarcity of labour of which the Arabs complain is probably traceable to the abolition of slavery by the late Sultan. It must be remembered that at the time of the budding of the clove-tree there is a sudden demand for labour upon the plantations, for if the buds are not promptly picked they burst into flower and become valueless. Mr. Portal is so well aware of the critical condition to which the country has been brought by the over-production of cloves, that he is already looking out for other economic articles to be brought into cultivation when the Arab's day shall be done (a contingency which the consul foresees at an early date), and the land have passed into the hands of Indians and Europeans. From manioc (tapioca), sago, coconuts, pineapples, and aloe Mr. Portal expects something. The plants already grown wild in profusion, and with a little care and intelligence might become profitable—the aloe and pineapples specially on account of the valuable fibre they yield. Vanilla, he thinks, might also become a profitable culture. The French missionaries in Bagamoyo, on the German coast opposite, already grow it, and assert that it pays them well. Chillies grow plentifully all over the eastern and southern parts of the island. Next to cloves and coprah they are the most important Zanzibar product. During the period from the beginning of this year until October 13th, 112,179 rupees' worth of them were shipped—half going to London, the remainder going to New York and Marseilles.

Until the English stepped in to rot the Sultan's tottering house in order, no official statistics or accounts of any value were kept in the island. No records were made of shipping; the lighthouses around the coast were left crumbling to pieces, and the only object to which the Government appeared to apply itself with sympathetic ardour was the collection of taxes. Mr. Portal has but one term to express the cause of all the wretchedness in Zanzibar—"Arab domination"—now, fortunately, in process of abolition.—*Chemist and Druggist*, March 19.

TEA AND COFFEE.

Now that there is so much talk about tea and the good and evil effects resultant on its use and abuse, perhaps a few words of reminder concerning Professor Sir William Roberts' researches on food accessories would not be out of place. They were noticed in the *Nineteenth Century* by Dr. Burney Yeo, February, 1886, and as far as I can remember, have been practically uncontradicted, in the Reviews at least, by anyone entitled to a hearing on such matters. Sir W. Roberts had already presented to the world a mass of most valuable information derived from his careful researches on the "digestive ferments" in his lectures delivered before the Royal College of Physicians in 1880. His later researches on "food accessories and their influence on digestion" are equally important, and more easily grasped by the lay mind. The results are, in some respects, as Dr. Yeo remarks, so novel and unexpected, and they contradict so many apparently unfounded assumptions, that they cannot be too soon too widely known.

This was written in February, 1886. We are now in February, 1892, and yet the general public seem as ignorant as ever, to judge by the current newspaper gup. It seems perhaps too much to expect that even a dozen readers will change their opinion and their practice concerning tea and coffee. Let us hope for the best, however. Many people are of the opinion that tea and coffee, though nice, are naughty, and have a vague idea that drinking such beverage is against the natural habits of natural man. Others again swear by tea and scold at the idea of any harm accruing to its votaries in whatever way and whatever quantity they drink it. But, as Sir W. Roberts remarks, man is now a very complex feeder; he has departed, in the course of his civilisation, very widely from the monotonous uniformity of diet observed in animals, in the wild state. These generalised food customs of mankind are not to be viewed as random practices adopted to please the palate or to gratify our idle or vicious appetites. These customs must be regarded as the outcome of profound instincts, which correspond to important wants of the human economy. They are the fruit of colossal experience, accumulated by countless millions of men through successive generation. They have the same weight and significance as other kindred facts of natural history, and are fitted to yield to observation and study lessons of the highest scientific and practical value. It is unnecessary to describe here Sir W. Roberts' methods of investigation; they are fully set forth in his volume and they are alike admirable for the ingenuity of their conception and the laborious accuracy of their prosecution. I shall concern myself at present only with that part of his researches which deals with tea, coffee and cocoa, merely mentioning that he deals at length with wines and all alcoholic beverages, giving too ardent Temperance-wallahs many a sharp rap over the knuckles, none the less effective if indirect.

Tea exerts a powerful retarding influence on salivary digestion, coffee and cocoa a comparatively feeble one. Sir W. Roberts estimates the medium strength of tea usually drunk at four to five per cent; strong tea may contain as much as seven per cent; weak tea as little as two per cent. Medium coffee has a strength of about seven per cent, and strong coffee twelve to fifteen per cent; cocoa, on the other hand, is generally weaker, not more than about two per cent; and this, he thinks, may be one reason why it is more suitable to persons with feeble digestion than tea or coffee. Tea exerts a powerful inhibitory effect on salivary digestion, and this appears to be entirely due to the large quantity of tannin it contains. It appears that tannin exists in two conditions in the tea leaf. One, the larger portion, is in the free state and is easily extracted by hot water; but about one-fourth is fixed and remains undissolved in the fully exhausted tea leaves. Some persons have supposed that by infusing tea for a very short time—only two or three minutes—the passing of tannin into the infusion would be avoided. *This is a delusion*; you can no more have tea without tannin than you can have wine without alcohol. Tannin, in the free state, is one of the most soluble substances known. If you pour hot water on a little heap of tannin it dissolves like so much pounded sugar. Tea infused for two minutes was not found sensibly inferior in its retarding power on salivary digestion to tea infused for thirty minutes. One gentleman of my acquaintance (says Sir W. Roberts) in his horror of tannin, was in the habit of preparing his tea by placing the dry leaves on a paper filter and simply pouring on the boiling water. In this way he thought to avoid the presence of tannin in his tea. But if you try the experiment, and allow the product, as it runs through the filter, to fall into a solution of per-chloride of iron, you will find that an intense lily black coloration is produced, showing that tannin has come through in abundance.

In order to diminish as far as possible the retarding influence of tea on salivary digestion, it should be made weak, and used sparingly, and it should not be taken *with but after*, the meal. There is another means, mentioned by Sir W. Roberts of obviating the retarding effect of tea on digestion, and com-

menced by him to the dyspeptic; *it is to add a pinch of bicarbonate of soda* to the tea when it is being infused in the tea-pot. He found that ten grains of soda added to an ounce of dry tea almost entirely removes this retarding influence. The infusion thus made is darker than usual, but the flavour is not sensibly altered, nor is the infusion rendered alkaline, for tea infusion is naturally slightly acid, and the soda, in the proportion mentioned, only just neutralises this acidity. It is a very general practice, I believe, at home, to add a pinch of soda to the tea, but not on account of neutralising the acidity, I am afraid, but to "soften" hard water. In other words, to precipitate excess of lime held in solution by the "hard" water, I make it a rule now to add the pinch of soda required, and I cannot perceive the slightest difference in the flavour of the tea. Taking my tea without milk or sugar, as I am in the habit of doing, I stand a better chance of detecting any unusual flavour than if I drank it in the usual way. My readers, however can readily judge for themselves. Coffee, unless taken in a very large quantity, has very little retarding effect on salivary digestion; this is explained by the fact that the tannin of tea is replaced in coffee by a substance called *caffeo-tannic acid*. Cocoa resembles coffee, and has but little or no effect on salivary digestion; the use of coffee or cocoa is therefore preferable to that of tea for persons of feeble digestion. Thus far on *salivary digestion*; we now turn to *stomach digestion*, which is a very different thing.

Tea and coffee both exercise a remarkable retarding effect on stomach digestion. There was no appreciable difference in the two beverages if they were of equal strength, but as coffee is usually made of greater percentage strength than tea, its effect must ordinarily be greater. Cocoa, also, had much the same effect if used of the same strength as tea or coffee, but when of the strength as ordinarily employed, its effect was inconsiderable. Strong coffee—*café noir*—had a very powerful retarding effect, and persons of weak digestion should avoid the customary cup of black coffee after dinner. A good deal has been said and is being said of the injurious effects on gastric digestion of tannin contained in tea. It has been alleged that meat fibre is hardened by tea, and that the coats of the stomach are liable to be injured by this beverage. These views are entirely theoretical. For people of strong digestion, the use of tea as a beverage is, when taken in moderation, of great benefit, at least so argues Sir W. Roberts. This also applies to coffee and cocoa. They serve, he maintains, the purpose of wholesomely slowing the otherwise too rapid digestion and absorption of copious meals.

One thing to be borne in mind, especially by ladies, is that tea, if taken *at the same time* as farinaceous food (such as bread, toast, porridge, cakes and biscuits), is much more likely to retard its digestion and cause dyspepsia than if taken a little time after eating. It is better to take one's five o'clock tea without the customary bread and butter or cake, than with it. Indeed, while there is little that can be said against a cup of hot tea as a stimulant and restorative, when taken about midway between lunch and dinner, and *without* solid food, it may, on the other hand, be a fruitful cause of dyspepsia when accompanied at that time *with* solid food. It is also a curious fact that many persons with whom tea, under ordinary circumstances, will agree exceedingly well, will become the subjects of a tea dyspepsia if they drink this beverage at a time when they may be suffering from mental worry or emotional disturbance. Moreover, it is a well recognised fact that persons who are prone to nervous excitement of the circulation and palpitations of the heart, have these symptoms greatly aggravated if they persist in the use of tea or coffee as beverages. The excessive consumption of tea amongst the women of the poorer classes is the cause of much of the so called "heart complaints" among them; the food of these poor women consists largely of starchy substances (bread and butter chiefly) together with tea, *i.e.*, a food necessary which is one of the greatest of all retarders of the digestion of starchy food. The effect a

coffee as a retarder of stomach digestion would be probably more felt than it is were it not so constantly the practice to take it only in small quantities after a very large meal; it is then mixed with an immense bulk of food, and its relative percentage proportion of food insignificant. To the strong and vigorous the slightly retarding influence on digestion may be, as Sir W. Roberts suggests, not altogether a disadvantage, but after a spare meal, and in persons of feeble digestive power, the cup of black coffee would probably exercise a retarding effect on digestion, which might prove harmful. It is also worthy of remark that in the great coffee-drinking countries this beverage is made not nearly so strong as with us. At home, and in India also, I am afraid, *good* always means *strong* coffee, often very strong coffee; but on the Continent they possess the faculty of making *good* coffee which is not necessarily very *strong* coffee, and which, therefore, as a beverage, is less likely to do harm. The great difference between English and Continental coffee is that the former make their coffee from a mixture of chicory and coffee dust, and consequently have to use large quantities to obtain any flavour at all from the decoction. On the Continent they either roast it themselves or buy freshly roasted coffee and grind it at home. This we do out here also, *why* don't we get good coffee? Of the three drinks therefore, cocoa may be ranked first, as being least harmful to digestion. Taken with proper precautions, however, tea and coffee may be safely partaken of, in most cases with much benefit to the drinkers.

—*Madras Times*.

CRAMPTON.

[A person's own instinct and experience are the best guides; and both are in favour of tea with milk and sugar.—*Ed. T. A.*]

THE CULTURE OF RHAMIE.

Many people know the value of rhamie, its growth and preparation, but for the edification of those who do not, we will explain. Rhamie is a native of the Sanda Islands, but has long been introduced in Upper Burma from China. This fibrous plant was originally confounded with China grass; however, it is now recognised that the two are essentially distinct, China grass being classified as *Boehmeria nivea*, whilst rhamie is furnished by the *Boehmeria utilis*. Both plants are of the nettle order and of considerable size, especially when they are improved by culture; but their leaves differ in colour, the former having a silver-white top, whilst the latter has greyish-green leaves. The fibre obtained from each plant is very similar in many respects, but that obtained from rhamie is far superior, being very soft and beautifully white, and does not break so easily when subjected to tension. As regards cultivation, rhamie presents many advantages. It is a hardy plant, very vigorous and healthy and when once planted, it will continue to flourish about twenty years with regularity, provided it receives a certain amount of constant care. It multiplies easily and rapidly, and can be planted at small expense. Its cultivation is simple and its crops very abundant; in dry climates three to four harvests a year can be reckoned on. With regard to its value rhamie certainly produces a better fibre than cotton or linen and one as glossy as silk.

Different fibres being of different thickness their relative value can best be judged by reducing them to a common denomination. Taking rhamie as the unit, we reach the following results:—

Thickness.	Tensile Strength.	Elasticity.	Strain.	Twisting
Rhamie .. 1	.. 1	.. 1	.. 1	.. 1
Flax .. 2	.. 2	.. 2	.. 4/5	.. 4/5
Hemp .. 3	.. 3	.. 3	.. 19/26	.. 19/26
Cotton .. 4	.. 4	.. 4	.. 4	.. 4
Silk .. 4	.. 4	.. 4	.. 4	.. 6

It will be thus seen that rhamie fibre is longer and more uniform than all the others, except silk. It is more solid, has more tensile strength, more resistance to twisting strain and more elasticity than linen or hemp, or even cotton, though the latter can be more

readily twisted. Inferior only to silk. Under the preparation to which rhamie is submitted, it receives the appearance of cotton wool or even silk thread. From its single or mixed fibres may be woven all kinds of stuffs from the finest to the coarsest. Mixed with wool, or with wool and silk, rhamie can be made into magnificent furnishing materials. Imitations of satins, simmings, and table linen can also be made from it.

I may add that all the imitation silks worn by the Karens and Thans are the produce of this fibrous plant. Another unheard-of use of this valuable fibre is the manufacture of steam pipes, which we hear is a remarkable Yankee invention, and of which we shall hear something more in this country before long.

The soil suitable for rhamie is a light one, such as chalk, sandy or alluvial; spots which can be easily irrigated. As to climate, the warmer the better. Having regard to all these different conditions, it is without doubt that this plant can be cultivated with advantage in parts of India and Ceylon.

Reproduction can be obtained by sowing, but the method most commonly adopted is to plant pieces of roots or thick slips. The nurseries should be made in a light soil similar to beds of a kitchen garden.

As carting up has to be done later, it is well to render it more easy by preparing the grounds in furrows. The plants are placed a few inches apart till they are strong enough to be transplanted.

During the whole time of preparation, the nursery soil must be well manured and kept free from noxious weeds. It being a strong plant which will occupy the soil for many years, plantations may be made. In that case the soil must be prepared to a depth of 2½ to 3 feet, which can be done by ploughing, the best results being obtained by the most carefully prepared ground.

When the plants grow to the height of 2½ feet, the tops are then cut, but the fibre in this instance is very inferior; second weeding is then necessary: then new sputs are allowed to spring up. When the lower parts of those shoots turn brown, a new cutting is proceeded with. This time the fibre is of good quality and the plantation well established. To preserve it, it is only necessary to weed between each cutting down. The ground should be well manured, as rhamie, like all other plants, is fruitful in proportion to the manure with which it is supplied. For this purpose horse or cow's dung is found very suitable.

The crop once gathered has to be prepared. It is an established fact that rhamie cannot be retted the fermentation set up by that process would destroy the qualities of the fibre. Separation by hand is a very long operation, and cannot be employed unless labour can be obtained very cheaply; it is therefore mainly effected by machinery. Many have been tried but their defects, such as breaking or deflecting the fibre, have caused them to be abandoned.

The fibre once obtained, it has to be washed with gum and bleached; then it is ready for combing, carding and other textile purposes.

It has been estimated that a plantation of five acres will nourish 80,000 plants and the produce of three cuttings in one year will give 159,000 lb. of stems, which will yield 3,200 lb. of fibre, the market value of which is three annas per pound.

Many people are experimenting with various processes was for extracting the fibre cheaply and quickly. Up to the present no results are quite satisfactory. However, it would be well for capitalists and manufacturers in India to try experiments in this direction, as it is one of the most important industrial problems of the day.—*Indian Textile Journal*.

NOTES ON PRODUCE AND FINANCE.

THE INDIAN TEA DISTRICTS' ASSOCIATION AND NEW MARKETS.—At the meeting of the Indian Tea Districts' Association, held on Tuesday, the question of new markets was discussed and the necessity for active

co-operation between India and London urged. We are glad to find that preparations are on foot for obtaining the sinews of war, and that there are signs of activity in the right direction. On the subject of new markets, Messrs. George White and Co., in their annual report, have the following:—As still larger areas will be available, both in India and Ceylon, for the production of tea, it is evident that fresh outlets, outside the United Kingdom, must be sought for and exports encouraged. With this object in view, arrangements are already being made to bring British-grown tea before the world at the Chicago Exhibition next year. Steps have been taken to solicit a grant from the Indian Government, and to direct the attention of those interested in the cultivation of tea there to the importance of being adequately represented. Hitherto the expenses attending exhibitions have fallen principally on London agents and brokers, while comparatively very little has been raised for the purpose in India. It is therefore, now proposed that a small sum per acre shall be contributed by each estate in furtherance of the above project, which appears a fair method of raising funds absolutely necessary, not only to enable India to maintain her position, won after many years' struggle, but to open out other channels for her increased output. We also learn that considerable sums have been promised by the Government and planters of Ceylon. It is hoped that altogether about £2,000,000 will soon be forthcoming to forward the industries of the island on that occasion. The interests of these two countries being to such a great extent identical, it seems of vital importance that they should, if possible, adopt a common policy in opening up new markets for their produce. Increased shipments have been made both from Calcutta and Colombo to other countries besides Great Britain, the figures for the past two years, from May 1st to Feb. 5th, being:—India: 1891-2, Australasia, 4,288,000 lb.; Bombay (chiefly for Persian Gulf) 3,058,000 lb.; Sundry Ports, 566,000 lb.; America 180,000 lb.; total, 8,902,000 lb. India: 1890-1, Australasia, 4,545,000 lb.; Bombay (chiefly for Persian Gulf) 742,000 lb.; Sundry Ports, 213,000 lb.; America, 118,000 lb.; total 5,618,000 lb. Ceylon: 1891-2, Australasia, 2,310,000 lb.; Bombay (chiefly for Persian Gulf, 460,000 lb.; Sundry Ports, 598,000 lb.; America, 144,000 lb.; total, 3,422,000 lb. Ceylon: 1890-1, Australasia, 2,010,000 lb.; Bombay (chiefly for Persian Gulf), 107,000 lb. Sundry Ports, 182,000 lb.; America, 142,000 lb.; total, 2,441,000 lb. The low prices current here during the past eight months have, no doubt, been beneficial in developing the export from London to the continent of Europe, as for the first two months of this year India totalled 737,000 lb and Ceylon 414,000 lb. against 423,000 lb. and 161,000 lb. respectively for the same period in 1891.

TEA A LA CHAMBARD.—One of the difficulties met with in opening up new markets for tea on the Continent arises from the fact that in France and elsewhere the idea prevails that tea, as the British drink it, is a medicine, and a very strong one to be carefully avoided when the consumer is in health. This notion, which lingers now among the French, is likely to be strengthened by the advertisement of a certain M. Chambard, who advertises "Chambard's Aperient, Purifying, Diuretic Tea," which we are told, is "solely composed of the leaves of certain plants and flowers and is a very reliable purgative." We fear that this tea of M. Chambard's may be confused in the French mind with tea from India and Ceylon, which is now procurable in Paris, but possesses no medicinal qualities of the kind mentioned by M. Chambard.

INSURANCE OFFICES AND THEIR TARIFFS IN CEYLON.—We publish some correspondence on this subject between Mr. Martin Lenke, Secretary of the Ceylon Association in London, and the Secretary of the Fire Offices Committee. As the latter shifts the responsibility on to other shoulders, the owners of which also decline to accept the burden, the matter is left precisely where it was.

ANALYSIS OF CHINA TEA.—The China tea which finds its way over here is not always as pure as it should be, as will be seen from a report by Mr. W. C. Samuel, tea analyst to the Custom House,

to the Commissioners of Customs on examinations of tea under Section 30 of the Sale of Food and Drugs Act, 1875. He states:—"In submitting the annual return of tea analysed by this department under the Sale of Food and Drugs Act, 1875, for the year ended Dec. 31st, 1890, I beg to report that the total number of samples analysed during the year was 437, viz., 84 green faced tea, 10 green not-faced tea, 96 green caper tea, 154 black congou tea, 64 black dust tea and 29 black siftings. Of these 334 samples were found on analysis to be satisfactory, and the importations represented by them were delivered on the certificate of the analyst. On the remaining 53 samples, representing 516 packages of doubtful and unsound teas, the results of analysis were reported to the Board with the following results: 1 sample, representing 5 packages, was admitted to home consumption; 41 samples, representing 501 packages, were restricted to exportation owing to the presence of exhausted leaves, damage, or other causes within the Act; 8 samples, representing 139 packages, were refused admission, as unfit for human food; 3 samples, representing 71 packages, were on analysis found to be teas that had previously been imported, and ordered to be exported. They were this year re-imported and re-labelled as new season's teas. This fact, with the analysis, was reported to the Board, and the whole of the parcel of 71 packages were ordered to be seized under the Merchandise Marks Act."

LAST WEEK'S TEA MARKET.—The Indian tea market, says the *Produce Markets' Review*, has developed more activity, and the demand generally has shown an improvement. This, coupled with moderate supplies, has made prices somewhat firmer for the more desirable common grades, but it will require a much brisker demand before any material reaction from the present low prices take place. Judging from the report of recent sales held in Calcutta, the bulk of the tea consisted of the lowest sorts, which means that a considerable proportion of the coming imports will be of these descriptions. On the other hand, the values of the medium and finer sorts are still moving upward, and, judging from the manner in which those teas have been bid for, buyers appear to hold but moderate stocks. This being the case, a strong market may be anticipated for some time to come, particularly as many of the owners of gardens from which the better class teas are produced have thus early disposed of the whole of the past season's growth. The quantity of Ceylon offered continues extremely small, and, although no very considerable trade has been done, the feeling at public sale has been in the direction of firmer prices. Very little improvement has been apparent in quality, but the season is approaching when better teas are to be expected. The arrivals for the week were:—The "Legislator" and "Bengal," from Calcutta and Colombo; "Ningebow," "Jelunga," and "Maasilis," from Colombo.

A NEW COFFEE COMPANY.—Under the title of the *Courge Coffee Estate Company, Limited*, a new company has been registered, with a capital of £200,000, in £10 shares. Object, to acquire lands and buildings, and to develop and turn to account the same by planting, clearing, draining, and building thereon; generally to carry on business as planters, growers of all kinds of produce, merchants, importers, and exporters in all their respective branches. The first subscribers, who take one share each, are:—N. Brown, 7, Princess Road, Brownwood Park, South Hornsey, N.; W. G. Smith, 87, Haldon Road, S. W.; T. Hoare, 26, Hayden Park, Wembleton; R. Moffat, 14, Grand Road, Canonbury, N.; T. R. Dick, 25, Regina Road, Tollington Park; R. A. McClare, 7, Nelson Road, Hornsey; and D. H. Slimec, 43, Alkham Road, Stoke Newington, N. Registered without special articles of Association.

COFFEE IN COLOMBIA.—The State of Colombia is going in heavily for coffee cultivation. In the single district of Los Santos 120,000 coffee trees have been planted this season, and the plantations are in a most promising condition. Some idea of the

steady growth of this branch of Colombian agriculture may be gathered from the fact that the exports of coffee from the Republic, which in 1885 amounted to only £31,533 had reached in 1890 £116,259. The report states that there is an abundance of fertile land suitable for coffee-growing in the district.

LADY TEA MERCHANTS.—Another rival to the regular tea-dealer has arisen. The lady as tea-merchant is quite the latest development. A Ladies' Own Tea Association have secured premises in Bond-street, and there independently import, blend, and sell their tea. Their ambition is to have "lady agents" in every town in the kingdom. *H. and C. Mail*, March 25.

THE OUTLOOK FOR INDIAN PLANTERS.

To the Editor of the Home and Colonial Mail.

Sir,—As your readers would doubtless notice from the tenour of a letter which I sent to you last week, it appears to me that very much misapprehensions exists in regard to the relative economic capabilities of India and Ceylon respectively to produce tea at a profit.

I accordingly venture to make one or two remarks on certain points referred to by your correspondent "Scrutator," in last week's issue.

"Scrutator," of course, writes as a Ceylon planter, and I confess frankly to writing as an Indian one. He points out that a great and serious difference between the two countries lies in their cost of production, and then proceeds to assert that Ceylon is capable of laying down her teas several pence per pound cheaper than India; and he adduces, in proof of this, first, an assertion that Ceylon teas are laid down at a cost of 6½d a lb. and second, statistics, shown in black and white, in regard to the cost of the India, companies' production from Mr. Burnshaw's well-known statement for the season 1890. Might we ask for a similar statement, worked out on the basis of publicly published reports for a large number of Ceylon companies? No doubt the large and most favourably situated Ceylon companies can lay down at a low cost, despite the comparatively small acreage product and the more expensive fuel and wages of that island; but what about the thousand and one smaller and less thoroughly organised estates?

In regard to Mr. Burnshaw's statement, I would make the following remarks. The greater number of the London companies there represented are in the province of Assam proper, whence come the strong and pungent teas which realise in the London market pence per pound more than either Ceylon teas generally or than the general average of Indian teas. Under this category come eighteen out of the twenty-seven companies. Many of those gardens also are old concerns, which have not yet freed themselves from the old traditions of expensive working, although they are beginning to hestir themselves in that respect.

Even as regards modernly organised Assam companies, despite the high cost of importing fresh labour, there is no doubt that, should they be driven to extremities, they could immensely reduce their cost of production, many of them having fortified themselves in good times by going in for heavy "batterments," which have been paid for out of revenue.

The enormous areas now under tea in the districts of Cachar, Sylhet, and Western Dooars are only represented in Mr. Burnshaw's list by five companies—chiefly small ones—the great bulk of the properties in these districts being either *Ouleuta* companies or private ownerships, and the capabilities of cheapness in their working having practically no limit if competition should place them on their mettle.

Another point is that despite the comparatively high cost of production of those companies they showed on average about 2½d. per pound profit; and further it should be pointed out that the year 1890 was the year when the working cost was largely enhanced by the rise in exchange.

The only gardens, except a few moribund and

worked out gardens, chiefly in Cachar, which may have difficulty in reducing their cost are the gardens in the Darjeeling district where yield is small, but this is largely compensated for by the fact of their wonderful capabilities of producing a tea of exceptional merits, for which, in fairly favourable seasons, they can always command a high range of prices.

Your correspondent, however, will not have done harm if, by his letter, he may have aroused the Indian planters to the great importance of strict economy, consistent with efficiency.

As to your correspondent's suggestions for a remedy to the existing state of things, I cordially agree with him in the importance of, first, effecting economy so long as this is not done to the detriment of cultivation; secondly, organising for the opening out of fresh markets; thirdly, of keeping up the standard of quality so far as can be without too much enhancing the cost; but in regard to his fourth recommendation—"to absolutely desist from planting more land with tea" I would merely remark that, however this might be desired, it is that which there is not the least possibility of succeeding in doing, for the reason that by extension alone on the present existing companies provide against possible deterioration and by so doing alone can they expect to further reduce the poundage cost of their crop.—Yours, &c. OBSERVER.

—*H. and C. Mail*, March 25.

TEA IN DARJEELING, THE DOOARS AND THE TERAI IS THIS NOTICED BY THE *Darjeeling Standard* :—

The tea season may be said to have begun, plucking leaf having been commenced on some estates. The season is considered an early one, especially for gardens favourably situated as regards moisture; rain is much needed however, as the showers which fell three weeks ago were not sufficient to reach further than three or four inches below the surface of the ground, which has now become as dry as before. Although last season proved to be such a trying one for the tea industry, owing to the extremely low prices ruling for tea, yet there are very few of the gardens in this district which show a balance on the wrong side of the books, while most concerns have made a satisfactory profit. The published accounts of public companies in the district almost all show a dividend ranging from 3 per cent to 15 per cent; a result which must be gratifying to holders of tea scrip in these bad times. The accounts from the Dooars district are still more gratifying, as much as 40 per cent on the capital having been made in more than one instance; those from the Terai, however, are somewhat doleful, for although many of the best concerns have paid well, yet a large number have suffered loss; this is not to be wondered at in the face of the exceptional difficulties of the season. The death rate is said to have been exceedingly high, not only from cholera, but from influenza and fever of a specially malignant type, which carried off a much larger number than the former disease. The result of this was of course a great scarcity of labour, and consequently some managers had to temporarily abandon hundreds of acres of tea, whilst others resorted to special money inducements to obtain labour, a proceeding very like that described as "burning the candle at both ends." Such an unhealthy season for coolies has never been known before, and it is hoped will never occur again. The present prospects of coolie labour are unusually bright, food is scarce and dear in Nepal, and coolies are flocking in large numbers into British territory, where the resources are greater and a local scarcity much more easily remedied. Tea prophets tell us that the London market is not likely to open with a better tone than last year, the imports from Ceylon have already assumed gigantic proportions, and it has become quite a regular part of Tea Brokers' reports that there is a superabundance of teas of a "common" description, whilst good parcels are still well competed for. Our friends the planters will no doubt find it their best policy to go in more than ever for the fine flavoured teas for which this district is famous.

WILSON, SMITHETT & CO.'S CEYLON TEA MEMORANDA FOR 1891.

London, March, 1892.

The Ceylon Tea market during the year 1891 has pursued a remarkably uneventful course. During the first two or three months the strong statistical position of the article as a whole gave rise to considerable speculation in the "future" market, and caused a quite disproportionate advance in the quotations for low grade leaf tea, but the unexpectedly heavy arrivals from Ceylon, at this juncture, consequent upon an abnormally wet spring, speedily dispelled any fears as to possible short supply, and a reaction followed, from which the market never thoroughly recovered during the remaining portion of the year.

The weight of Ceylon tea offered in auction between January 1st and December 31st, 1891, amounted to 60,000,000 lb. or 50 per cent in excess of the supply in the previous year, and realised an average price of about 10½d per lb. against 10½d in 1890 and 1889.

On the opening after the Christmas holidays of 1890 a strong demand set in, establishing an advance of ½d to 1d per lb. on useful medium Souchongs and Pekoes; prices for all desirable leaf teas up to 1s per lb., also gradually hardened throughout January and February, but during this time ordinary Broken Pekoes experienced a flat and irregular market. At the close of February the artificial character of the "boom" in teas for "price" became more widely recognised; the high rates established had checked business in the country, and dealers being well stocked, this class of tea commenced at once to decline in value. Towards the end of March a slight recovery took place in teas up to 10d per lb., but above this price buyers acted cautiously. After Easter there was again a slight upward movement which was maintained throughout April until Whitsuntide, when the large supply coming forward had a very depressing effect upon the market. In June the demand tended more strongly towards really good liquoring teas, which commanded much more attention than they had received throughout the spring; common teas, on the other hand, were neglected. At the close of July the market had relapsed into extreme dullness and at this period the average price had receded from 1s in January-February to 8½d per lb., or as low as at the most depressed period in 1889, when, however, lower rates for common grades caused the reduced average, whereas now the fall extended over a much wider area. After the August holiday a good demand for really good to fine tea sprang up which lasted throughout the autumn, values gradually hardening, and at the end of October the average price had advanced to 10d per lb. During November the market showed less buoyancy but a better tone became apparent next month, and the year closed with firm rates and an average of 10½d per lb.

The list of estates, which we have tabulated this year, gives the results on 562 gardens, which have* sold over 20,000 lb. of tea during 1891, on the London market, under their own marks. On comparing these results with last year's it will be noticed that in the great majority of instances the largely increased yields have been disposed of at a marked reduction in the prices realised; this decline in value was mainly confined to the large bulk of ordinary quality tea, the range of prices being well maintained in those gardens favoured by elevation and climatic advantages. Portswood, which has increased its output by about 80 per cent, shows an average of 1s 4½d per lb. for the year against 1s 4d in 1890, this being again the highest on the list. A rise of 1d per lb. in the average accompanied by a very substantial increase in the yields of Chapelton, Gloudeven, Norwood, Morar, and Geatfell must be considered highly satisfactory, especially when the generally depressed state of the market in 1891 is taken into consideration, and serves to emphasize the fact that really good tea will almost always command the special attention of the trade. On numerous other estates almost equally satisfactory results are shown, as reference to the names of Bogawantalawa, Honfeld, Glenalpin,

Spring Valley, Invoy, Glenugie, Elbeddo, Gorthie, Monnt Vernon, Onvah Kellie, Frotoft, &c., will testify. Of the different districts, Bogawantalawa, the neighbourhood of Nawara Eliya, and Dimbula again head the list; the two former suffering a diminution of ½d and the latter 1d per lb. in the average price obtained: the greatest reduction is shown in the Kelani Valley, where the average was 9d against 10½d in 1890.

The exports during 1891 show very satisfactory extension, the actual figures being 2,100,000 lb., against 1,432,000 lb. in 1890. The Continental demand was considerably interfered with by the distress in Russia, occasioned by the failure of cereal and other crops, which gave rise to restrictions and prohibitions in exports, and consequently depreciated the rouble; despite this a fair trade has passed in Ceylon tea with Russia, and there is ample evidence that in that country particularly it is coming more and more into favour.

The trade with America has also developed considerably during the past season, and much pains are being taken to push Ceylon Tea at the World's Fair to be held at Chicago next year; evidence is multiplying on all sides that this branch of the trade will yet show a great expansion, and the despatch of a Special Commissioner from Ceylon should have very substantial results.

During the past year, which has been decidedly one of over-production, Ceylon has still further out-distanced its rivals in the race for popular favour. Up till last season China had the undoubted advantage, in that it practically commanded the market for tea for price, common Congou forming the basis of the blenders' operations. But now that the relative positions of China and East Indian growths have become reversed, Ceylon has demonstrated its ability to undersell its old rival, and to give a much better article at the normal price of "common Congou." It would also seem that the decline of the China trade is operating entirely to the benefit of Ceylon. The bulk of Indian tea, being much stronger and more rasping than Ceylon, is in great measure dependent on China for blanding purposes to render it more acceptable to the palate, whereas Ceylon needs none of this tining down to make it a pleasant and wholesome beverage. However this may be, a glance at the Board of Trade returns for the year will show that whereas the Home Consumption of China tea during 1891 fell off to the extent of over 5,000,000 lb., and Indian to the extent of 3,000,000 lb., that of Ceylon has increased to 16,700,000 lb. Reference has also been made to the over-production in 1891, and it may be advisable to devote some attention to the prospects of the future. The extraordinarily wet spring in Ceylon last year was productive of heavy flushing, and the yield on a great number of estates consequently almost doubled the estimates made. It was this unexpectedly heavy supply that upset the calculations of speculators on the "future" market and had such a depressing effect on the trade throughout the remainder of the year. The low rates afterwards established had the highly desirable effect of sending Ceylon tea rapidly into consumption, and it is very satisfactory to note that practically all the Ceylon tea imported since June last up to date has been delivered from the warehouses.

At the close of the year the apprehensions of the trade as to the supply of the forthcoming season were not allayed by the sanguine estimates formed of the probable yield of 1892, and the report was widely circulated that we should have between 80,000,000 and 90,000,000 lb. from the island, some going so far as to give a still more extravagant amount as our probable supply. Maturer reflection has considerably pared down this weighty total, and the most reliable authorities do not now estimate the exports for 1892 over 75,000,000 lb., and several causes are likely to still further diminish this total. Firstly, the heavy cold rains in January considerably reduced the amount we might reasonably have expected during the first two months of the year; secondly after the heavy flushing of last year some reaction will probably set in, the bushes being scarcely likely to prove so prolific in the coming season; and thirdly, the low rates current for common grades have induced many growers to adopt, at any

* Each of which has.—ED. T. A.

rate for a time, finer system of plucking, al which will probably limit the output, and with only about 70,000,000 lb. available for the U. K., our market should not be too heavily supplied.

Summary of Ceylon tea sold at public auction in London between January 1st and December 31st, 1891, estimated quantity in lbs. and average prices realised:—

Average Price for the year 10½d per lb., against 10½d in 1890, and 10½d in 1889.

The initial letters following the estate names refer to the mean elevation, as follows:—

L (low) sea level up to 1,000 feet; HM (high medium) 2,500 to 3,500 feet; HH (highest) above 5,000 feet; M (medium) 1,000 to 2,500 feet; H (high) 3,500 to 5,000 ft.

Galle	277,000	0 8½	0 9½

N. B.—Untraceable marks to the extent of about 4,500,000 lb averaging 8½d per lb are not included in the above estimate.

Home Consumption of China and East India growths ten years ago, five years ago and last year:—

China.	Indian and Ceylon.
1881... 112,158,000lb.	49,836,000lb. or 30½ per cent of the total
1886... 100,000,000	74,665,000 " 42½ " " "
1891... 50,817,000	149,250,000 " 74½ " " "

N.B.—In 1890 the consumption of Indian and Ceylon was 70½ per cent of the total. [Then follows a table of monthly deliveries of Ceylon tea, which averaged 4,457,000 lb. in 1891, the highest monthly delivery as yet being 5,486,000 lb. in June. The same month showed the highest import, viz. 6,480,000 lb.—Ed. C. O.]

BOARD OF TRADE RETURNS.

Imports and Home Consumption of tea from all countries during the past five years:—

	1891.	1890.	1889.	1888.	1887.
	lb.	lb.	lb.	lb.	lb.
From British East Indies.					
171,939,263	146,260,642	127,160,409	113,004,692	97,830,117	
From China.					
61,935,325	73,635,351	83,848,574	105,424,271	119,739,116	
From Other Countries.					
6,458,739	4,758,378	5,593,677	5,189,515	5,194,054	

Imports. 240,333,327 224,654,371 221,602,600 223,618,478 222,763,287
Home Consumption. 220,456,837 194,008,492 185,621,800 185,556,214 183,635,835

Of this total 98,841,931 lb. were Indian, 51,227,602 lb. Ceylon, 49,616,139 lb. China, and 2,671,165 lb. from other countries.

Of this total 101,961,666 lb. were Indian, 34,516,469 lb. Ceylon, 54,873,592 lb. China, and 2,656,745 lb. from other countries.

Of this total 124,408,798 lb. were British East Indian, 59,513,397 lb. China, and 1,699,600 lb. from other countries.

Exports of Tea (all kinds) during the past five years:—

1891.	1890.	1889.	1888.	1887.
lb.	lb.	lb.	lb.	lb.
132,983,334	336,967,137	35,661,900	37,976,240	34,741,390
† Of this total 3,339,898 lb. were Indian, 2,033,029 lb. Ceylon, 25,284,825 lb. China, and 2,265,652 lb. other countries.				
* Of this total 2,624,579 lb. were Indian, 1,431,931 lb. Ceylon, 31,493,125 lb. China, and 1,417,502 lb. other countries.				

INDIA, CEYLON & JAVA TEA.—MONTHLY REVIEW, SEASON 1891-92.

From Geo. White & Co.'s monthly review we take a few extracts:—

After the issue of our last annual circular on the 20th March, 1891, the market for India tea showed little alteration up to May, when common to medium declined in value, owing to the dealers not being able to move off their stocks of these grades brought at top prices, and business continued dull until the arrival of the new crop, the first invoice of which was sold on the 4th June. By the end of the month only 2,900 packages New Season's had been brought to auction, against 3,600 packages in 1890. These first arrivals, although, as is usual, below the average, were considered about up to those of last year in quality. Dealers at this time were clearing out their holdings at considerable loss. The fall in value is indicated by the quotation for "Type" Pekoe Sou-chong, which in March, 1891, ranged from 10 3-16th d to, 10 11-16th d per lb.; on the arrival of New Seasons, in June, fell to 9 2-16th d per lb., and has continued to shrink during the subsequent months, as will be seen below.

Heavy sales of Ceylon tea took place during April, May and June, the result of excessive flushes. Quality was consequently not maintained, and this, together with a quiet demand, caused the monthly average to fall from 11½d per lb. in March to 9½d per lb. in June. The market was fully supplied with Java Teas. Fine, and those with "point," sold well, but prices declined for ordinary and common.

NOVEMBER, 1891.

The largest monthly total of India on record was reached, sales comprising 186,800 packages (about 16½ million lb.), of which 133,000 packages, representing garden invoices, sold at 9d per lb., against 10½ for 91,000 packages in 1890. Deliveries were still increasing as compared with the previous November. The heavy weight of tea sold taxed the capacity of buyers, and quotations for all common and ordinary gave way, fair Pekoes and Pekoe Souchongs being 3d per lb. under those of March and April. Fine and finest were, however, firmer.

Quotations for "Type" Pekoe Souchong ranged from 6 14-16thd to 7 4-16thd per lb.

For the past six months deliveries of India tea exceeded those of the previous year—viz., 52,763,000 lb. against 50,407,000 lb. Ceylon increased to 30,265,000 lb. in the same period against 21,261,000. Java deliveries were 1,865,000 lb. as compared with 1,992,000 lb. Cbins. &c., receded to 36,891,000 lb. against 43,860,000 lb.; the complete figures from 1st July to 31st Dec. being 121,784,000 lb. against 117,520,000 lb. in 1890. After deducting the quantity exported—viz., India, 2,137,000 lb.; Ceylon, 1,344,000 lb.; China, &c., 14,014,000 lb.; Java, &c., 1,438,000 lb.; in all 18,833,000 lb., the total home consumption for the six months stands at rather under 103 million lb.

JANUARY, 1892.

The market opened for Indias, after the holidays, on Monday, the 4th, with the heaviest sale recorded to that date, 24,700 packages being offered, though on the following Monday 25,600 packages were brought forward, which quantity has not yet been exceeded, and the total for the month was 165,000 packages, of which 110,000 packages, representing garden invoices, brought 8½d per lb. average, against 11½d per lb. for 104,000 packages in 1891. At first there was a good demand at prices fully up to those ruling before Christmas, but later, owing to dull trade, partly caused by the influenza epidemic, there was less

spirit, and rates declined for common and medium. One of the features of the month was the high quotation established for Choico Darjeelings and Assams.

Quotations for "Type" Pekoe Souchong ranged from 6 8-16d to 7 1-16d per lb. against 8 7-16d to 9 9-16d per lb. last year.

Sales of Ceylons were resumed on the 5th, and during the month 68,800 packages were brought to the hammer, realising an average of 9½d per lb. against 11½d per lb. for 43,000 packages in 1891. In consequence of the large proportion of common to medium and the quiet state of business, prices fell away for these descriptions until the average, which, at the beginning of the month was 10½d per lb., declined to 9d per lb. at the close. Fine and finest, however, were wanted, and remained firm.

Javas totalled 2,200 packages; sold at an average of 7d per lb. against 8½d per lb. for 1,800 packages last year. There was a fair demand, principally for export, and some good prices were obtained for the best lines.

MARCH, 1892.

India auctions to date total 63,700 packages, of which 44,000 packages, representing garden invoices, realized 8½d. per lb. against 11½d per lb. obtained for 40,300 packages in the same month last year. Owing to the smaller supplies rather a hotter tone prevailed for useful leafy kinds and fine and finest broken pekoes. Common, especially broken and low broken pekoes, however, were easier. Prices later improved for most kinds.

Quotations for "Type" pekoe souchong ranged from 6 3-16th d. to 6 8-16th d. per lb. against 10 3-16th d. to 10 11-16th d. per lb. during March 1891.

Sales of Ceylons for the past three weeks have aggregated 43,300 packages, the average for which was 9½d per lb. against 11½d per lb. for 53,000 packages for the month last year. Moderate arrivals gave buyers more confidence. Common grades sold steadily at the low quotations previously established. Medium sold irregularly with an upward tendency. Fine and finest generally firm.

About 800 packages of Javas have been offered, the average for which was 7d per lb. against 8½d per lb. for 6,900 packages in March, 1891. Continental buyers continued to support the market, and some good prices were obtained for fine lines.

GEO. WHITE & CO'S ANNUAL INDIA, CEYLON AND JAVA TEA REPORT.

LONDON, 31, FENCHURCH STREET, E. C.,

March 21st, 1892.

INDIA.—In reviewing the course of the India Tea market during the present season, and comparing it with the previous one, the principal difference noticeable is in the quotations for common and medium grades; for whereas at the date of our last annual report on 20th March, 1891, the value of fair Pekoe Souchong had been forced up to 10d per lb.* and Pekoes to 11d per lb. partly by operations in the London Produce Clearing House they are now selling at 5½d per lb. and 7d per lb. respectively. This serious decline is no doubt consequent on the large proportion of these descriptions which has come forward, partly due, perhaps, to coarser plucking, and also to climatic influences, which, although in many districts inducing a large yield, were unpropitious to the manufacture of fine tea. It would appear that, since the reduction of the duty, consumers prefer to pay rather more for a better grade, and that consequently heavily supplies of common and poor liquoring teas cannot be dealt with here, except at a range which, on many estates, cannot repay the cost of manufacture, freight, &c. The effect of reduced prices, so far as proprietors are concerned, has, however, been minimized by the lower rate of exchange ruling for the rupee during the greater part of the present season, the average being about 1s. 5d., against 1s. 7d. Good medium grades have not shown much fluctuation in value, and

* Spot Quotation for "Type" Pekoe Souchong, 10 7-16d per lb in 1891, against 6 7-16d per lb today.

fine and finest, owing to their comparative scarcity, sold well and at gradually hardening rates after Xmas.

Total deliveries for the twelve months ending 31st December, 1891 were disappointing, being 101,194,000 lb. against 102,845,000 lb. in 1890. There is no doubt that the high scale established in the spring months for teas under 11d. per lb. exercised an unfavourable influence on the clearances for home consumption during a great portion of the year. Dealers were encumbered with a considerable stock of these grades, which they were unable to dispose of, owing to the unexpectedly heavy supplies from Ceylon, selling at lower rates. This rendered buyers very cautious, as they were suffering under serious losses. Since October, however, an improvement in the deliveries is noticeable, which it is to be hoped will be more marked in future months, and to which the cheap rates current for fair liquouring Teas should conduce.

The quality of the crop has, on the whole, been below the average, though some invoices from Darjeeling and Assam have been exceptionally fine. Not only has the yield been increased, but shipments have again come forward more rapidly, so that in the autumn months it was not always feasible to regulate the public sales as was done to such advantage in the previous year. By the 31st December about 63 million lb. had been sold, against 53½ million lb. in the same period of 1890, and to date nearly 95 million lb. against 87½ million lb., so that the remainder to be disposed of will probably not much exceed that left to be dealt with at this time last year, reckoning the crop weigh out 112 million lb in London.

Ceylon.—The Ceylon branch of the trade has shown a further marked expansion, the imports and deliveries for the eight months ending 29th February last having both increased about 12 million lb., as compared with the same period in the previous season, when the addition was 7 million lb. The same causes which brought about full supplies of common and medium tea from India, singularly enough seem also to have prevailed in this island during the early part of 1891. Heavy flushes came on so rapidly that difficulty was often experienced in keeping pace with them. Consequently the crop was unexpectedly heavy, with a superabundance of inferior quality. This caused a gradual decline in the monthly average from 1½ per lb. in March to 9½ per lb. in August, since when it has fluctuated between 9½ per lb. and 10½ per lb. On the other hand, full prices were obtained throughout the season for fine-flavoured teas, and those estates which were able to send them benefited accordingly. It is, no doubt, satisfactory to owners of gardens that, with a lower exchange, 741,600 packages were disposed of in the year 1891 at 10½ per lb. against 545,000 packages at 10½ per lb. in 1890, from which it may be inferred that reduced quotations have further stimulated consumption, so that the total clearances of Ceylon tea for home use exceeded those of China, &c., for the twelve months ending 31st December, 1891, being 51,000,000 lb. against 49,000,000 lb.

Java.—Chiefly owing to the severe drought in Java during the manufacturing season, shipments to this country for the past eight months were considerably restricted. Quality on the whole has been well maintained, and in consequence of the demand for export these descriptions have often realised above the prices current for similar teas of other growths.

Exports.—Shipments of India and Ceylon tea to the Continent, &c., from London during the past eight months have shown a considerable expansion, as will be apparent on reference to the following figures:—

	India.	Ceylon.
	lb.	lb.
From 1st July, 1891 to end of February, 1892	2,874,000	1,658,000
From 1st July, 1890 to end of February, 1891	1,604,000	911,000
and for the 12 Months ending 31st Dec. 1891	3,340,000	2,093,000
and for the 12 Months ending 31st Dec. 1890	2,724,000	1,432,000

The distribution for 1891, being as under:—				
Continent of Europe.	United States	Canada, India, Ceylon.	Other Countries.	Total.
lb.	lb.	lb.	lb.	lb.
1,840,000	660,000	600,000	210,000	3,340,000
1,049,000	419,000	414,000	211,000	2,093,000

The undermentioned averages have been obtained here this season, from 1st July to the end of February, compared with the two previous ones. During July and August especially, a good many fine China Black Leaf Congous were disposed of by private contract, which renders it difficult to arrive at an estimate, so far as that country is concerned, with much exactitude. The one given must, therefore, be taken as approximate.

	1891-92	1890-91	1889-90
India	... 9½d	... 11d	... 10½ per lb
Ceylon	... 9½d	... 11½d	... 11½d "
China	... 8d	... 9½d	... 7½d "

[Figures for home consumption and export are then given.—Ed. T. A.]

These figures seem to indicate that the marked expansion expected in the Home Consumption, after the reduction of the duty on 1st May, 1890, has not yet been realised; the increase between 1890 and 1891 being on the same scale as between 1889 and 1890. At the same time, however, owing to the gradual displacement of China by the stronger teas from India and Ceylon, the quantity actually drunk is more than appears from the weight in pounds. The diminished export is no doubt due to the larger direct orders sent from Russia and the Continent to China, and also to the famine prevalent in the former country.

Should trade, therefore, progress on the ordinary lines, the total deliveries in the coming season for both Home Consumption and Export, it is reasonable to expect will be, in round figures, about 245,000,000 lb.

Of this India will probably send	...	116,000,000
Ceylon	"	75,000,000
Java	"	4,000,000
leaving China to furnish	...	50,000,000

245,000,000

Nothing reliable as to the size of the 1892 India crop has yet come to hand.

The latest estimates of the Ceylon output for the year 1892 vary from about 75 to 80 million lb. (though some more sanguine expect 85 million lb.), of which say 5 million lb. will be required for shipment to the Colonies and other countries direct.

Java will probably send more than in the present season, supplies having been curtailed on account of unfavourable weather.

[Then follow figures for seventeen seasons, during which imports from India rose from 25½ million pounds to 101, the estimate for 1892 being 112,000,000. Ceylon increased from 200 lb. to over 50 millions, the estimate for 1892 being 64 millions. Total British-grown rose from 25½ millions to over 151, the estimate for 1892 being 176 millions. China has gone down from 149 millions to 69½, the estimate for 1892 being 66 millions. The total of all kinds has increased from 174½ to 221 millions, the estimate for 1892 being 242 millions. Consumption has increased from 446 lb. per head to 520 lb.—Ed. T. A.]

Duty, until 30th April, 1890, 6d. per lb., afterwards, 4d. per lb.

N. B.—Transshipments for the Continent, on arrival from China, are not included in the above. Prior to season 1885-86, the Ceylon figures given represent the total exports from Colombo, the proportion shipped from there to foreign ports being inconsiderable. Shipments from Japan and Java are not taken into account, the former being unimportant and the latter varying considerably in different years, according to the Continental demand.

PROSPECTS.—As still larger areas will be available, both in India and Ceylon, for the production of tea

it is evident that fresh outlets, outside the United Kingdom, must be sought for and exports encouraged. With this object in view, arrangements are already being made to bring British-grown tea before the world at the Chicago Exhibition next year. Steps have been taken to solicit a grant from the Indian Government and to direct the attention of those interested in the cultivation of tea there, to the importance of being adequately represented. Hitherto, the expenses attending Exhibitions have fallen principally on London agents and brokers, while comparatively very little has been raised for the purpose in India. It is, therefore, now proposed that a small sum per acre shall be contributed by each estate in furtherance of the above project which appears a fair method of raising the funds absolutely necessary, not only to enable India to maintain her position, won after many years' struggle, but to open out other channels for her increased output. We also learn that considerable sums have been promised by the Government and planters of Ceylon; it is hoped that altogether about £200,000 will soon be forthcoming to forward the interests of the island on that occasion.

The interests of these two countries being to such a great extent identical, it seems of vital importance that they should if possible adopt a common policy in opening up new markets for their produce.

Increased shipments have been made both from Calcutta and Colombo to other countries besides Great Britain, the figures for the past two years, from 1st May to 5th February, being:—

Australia.		Bombay.		Soudry.		America.		Total.	
Asia. Chiefly for Ports.									
Persian Gulf.									
India.									
lb.	lb.	lb.	lb.	lb.	lb.	lb.	lb.	lb.	lb.
1891-2...	4,288,000	3,058,000	566,000	180,000	8,092,000				
1890-1...	4,545,000	742,000	213,000	118,000	5,618,000				
Ceylon.									
lb.	lb.	lb.	lb.	lb.	lb.	lb.	lb.	lb.	lb.
191-2...	2,310,000	460,000	508,000	144,000	3,422,000				
190-1...	2,010,000	107,000	182,000	142,000	2,441,000				

The low prices current here during the past eight months have, no doubt, been beneficial in developing the export from London to the continent of Europe, as, for the first two months of this year, India totalled 737,000 lb., and Ceylon 414,000 lb., against 423,000 lb. and 161,000 lb. respectively for the same period in 1891.

MANUFACTURE.—It seems probable, however, notwithstanding the assistance indicated above, that supplies will tax our consuming powers, and, therefore, planters should aim at a smaller output and better quality. We would draw attention to the following extract from our last annual circular, bearing on this subject which will also apply to the coming crop:—

“Heavy shipments being expected from all the producing countries, it behoves British planters to use every endeavour to prevent the market being flooded with mediocre teas of poor liquor. They will, therefore, probably find that by plucking a little finer than usual they will make much better tea, and in the long run show a more satisfactory result financially, as the enhanced prices obtained will more than recoup them even should the total output be smaller.”

There is no doubt that during the past year owing to very heavy flushes, this in many cases was impractical, and a large proportion of coarse leaf was plucked, which realized insufficient to cover cost of making, freight and warehouse charges, the last two items falling proportionately heavier on low-priced tea. It would have been better if this had either not been plucked, or else consumed locally. Perhaps it might be feasible to use some of the dust and coarse leaf in the manufacture of Brick Tea, which is largely made in China for shipment to Mongolia. Many planters encouraged by the high rates ruling last spring for Pekoo Souchongs, no doubt were induced to go in for quantity with the result that, though their output was increased, the average price suffered, for it is not the tea which costs least to make, that as a rule will be found to pay best. Consequently moderately fine plucking with very careful supervision during the process of fermentation and manufacture,

should under most circumstances prove the more remunerative.

SIZE OF BREAKS, STYLE OF PACKAGE.—The growth of the trade in British-grown tea renders it necessary to economise the time of buyers as much as possible, as, when sales are heavy, the samples to be tested are often more than can be properly gone through. Although the minimum for ordinary breaks remains at 12 chests*, 18 half-chests*, and 30 boxes* many of the dealers do not look at parcels of this size, in fact, so far back as in 1887, some decided not to taste anything less than 20 chest lines. To ensure full competition, therefore, for all excepting choice quality, the breaks should be as large as possible and invoices should not represent too many descriptions. The following assortment will generally be found to answer, viz.: a first class Broken Pekoo; a fine Pekoo; the bold leaf often sent with Pekoo to be left in the Pekoo Souchong; rough Souchong and Fannings to be equalised and packed as Broken Tea, thus making four kinds. Parcels containing Dust are un-a-table, therefore this should be sifted out and shipped separately.

Half-chests continue in favour, both with exporters and for home use, especially for pekocs. Leafy kinds, suitable for drinking alone, often sell well in boxes but, those packages should be not over 28 lb. gross to avoid the 1 lb. draft a load on those over this weight.

Factory-baked teas are still liked, many houses giving them the preference. In the majority of cases, the efforts of planters to attain regularity of appearance have been successful, and they have thus avoided the expense of bunking in London, which is of consequence low that the average price has fallen so low.

Economy in all things must be studied, and if the packing is regulated in accordance with the following scale, a considerable amount may be saved in the course of a season.

ANALYSIS OF CROP.—The 1891 crop from India has, on the whole been disappointing, fine teas being scarce throughout, as coarse plucking has been too general. Many of the Assams have been poor, and those gardens which have picked moderately fine have done well. Later invoices from many estates have shown better quality, and where autumn flavour has been combined with strength, some high averages have resulted. Cachars and Sylhets, with few exceptions, have been of an undesirable character, the weather evidently having not favoured manufacture. Darjeelings have shown much irregularity, but, when fine as in the case of some recent shipments, very satisfactory prices have been secured. Terais and Doars varied considerably, but those possessed of full flavour, have sold satisfactorily. The crop from the Kangra Valley has lacked the rich quality discernible in former years, and these, together with Kumaons, have generally been below the average.

From Travancore and other parts of South India there has also been a marked falling off in the special characteristics which formerly brought these teas into favour, and whatever may have been the cause, it is to be hoped it will be remedied in the coming season.

As is usual with an excessive crop, the quality of Ceylons has depreciated, and a very low range has been reached for common and ordinary kinds. The bushes must have suffered from the continuous and somewhat severe plucking to which they have been subjected, so that, in all probability, a different course will be followed on most gardens during this year. Those estates, which were so circumstanced as to be able to make fine Tea, have no doubt reaped the full benefit, these grades having been scarce.

As noticed above drought has much interfered with the Java crop, and consequently the shipments to this country have been curtailed. The improvement noticeable in make and cup during the last few years has been maintained, so that, while these Teas remain in favour with continental buyers, they are also more largely used in this country, especially by Blenders.

* Smaller lots than these are sold after the auction.

Correspondence.

To the Editor.

MR. JOHN BROWN'S ASTOUNDING CLAIM
RE COFFEE PULPERS DISPOSED OF.

72, Bishopsgate Street,
London, E. C. March 10th.

DEAR SIR,—In the report of the "Tea Roller Patent Case" in your overland edition of 18th ultimo, page 169, Mr. John Brown is reported as saying: "In coffee machinery I think I effected nearly all the improvements of any importance which were ever effected upon it."

To make use of a common remark, such a statement is "rather a large order," and out of respect to the memory of my late uncle, Mr. John Walker, I beg to submit the following facts:—

The Disc pulper, so well-known in all Eastern coffee countries, was invented and patented by Mr. Walker in 1860, and of that machine alone there has been made in Ceylon a larger number than all other coffee pulpurs put together, made either in Ceylon or the United Kingdom—and it is still being made in Colombo Iron Works.

About the years 1870-1871 the "half moon" cylinder cover was invented and patented by the late Mr. George Clarke (some time partner in the firm of John Walker & Co.), an invention which saved the coffee planters tens of thousands of pounds sterling, as it practically did away with all "cutting" of the bean.

Again the "Gearless" pulper was designed by Mr. Walter Lamont, who is still in your town and can speak for himself. Of the larger coffee machines the "Gearless" was in every respect the king of all.

But all this is no doubt to you and many of your readers a familiar tale. Perhaps some friend of the late Mr. John Gordon may see your paper and say a word on his behalf.

I assisted to make pulpurs in Kandy for about fourteen years, and I never heard of any improvements by Mr. John Brown. I knew of a very few home-made pulpurs, one of which now and then found its way to Ceylon, and wo in Kandy were always well pleased when one of these machines was erected at the entrance to a new district, as it made a good advertisement, and no more of same make went into that district. From 1870 to 1880, being the ten years of the good old coffee days, about eighteen pulpurs large and small, reached Ceylon from outside—perhaps those contained the improvements claimed by Mr. Brown.—I am, dear sir, yours faithfully, FRANK WALKER.

P.S.—On 4th October 1877 the *Ceylon Observer* contained a kindly notice of the old home of pulper making at Bogambra Mills.

TEA IN LEAMINGTON: "ONE OF LIP-
TON'S TEA ESTATES."

Leamington, England, March 24th.

SIR,—I have interested myself while here in collecting a few particulars as to the retail trade in tea, and by this post forward some trade circulars, catalogues, &c. I had some difficulty in obtaining them as the givers appeared to suspect something when I asked for them.

Messrs. Burgis and Colbourne have, as you will see, three stores in Leamington itself (a town of 27,000 inhabitants), but in addition to this they also supply many of the retail shops in the small towns and large villages in the vicinity. You will

probably be surprised to see that while their highest price for Ceylon tea is 1s 10d, that for China tea is 2s 6d! going up to 3s for the choicest import of 1891. You will also probably be surprised to learn from a leaflet I enclose that Ceylon tea may sometimes be drunk alone, the inference, of course, being that it is better when blended with China rubbish. By the way what is cinchona tea? (See page 9.)

The next firm is Melia & Co., who claim to be the greatest retailers of tea in England. They have two shops here, and about 50 more in other large towns. I do not know whether they (as they assert) get tea direct from the grower. (See page 63.) I noticed an old packing case marked Le Vallon in one of their windows.

But the most surprising and amusing of all is one of Lipton's circulars with a view of one of his tea estates in Ceylon. You will observe that in the left foreground there is a dock with a sea-going vessel in it. The tea grows right up to the quay, so that it is only a hop, skip and a jump from where the coolies are gathering tea leaves to the deck of the ship. There are no less than five tea-bousons on an area of about 25 acres, while a string of three elephants are carrying something (presumably tea), to be loaded in the vessel aforesaid. But the artist, not satisfied with this, has placed a large Moorish mosque in the middle of the tea. Oh! Mr. Lipton.

You will also note that Mr. Lipton does not even profess to sell pure Ceylon tea. The teas he sells are all blends.

As far as I have had opportunities of judging, Mazawattec tea has a very large sale. It is sold as being pure Ceylon tea, but, if so, is not of good quality. The retail price is 2s 4d per lb in lead packets. Yours faithfully, E. HOLLAND.

P. S.—I omitted to mention that the picture with the dock, elephants, etc., is named "One of Lipton's Tea Estates." Can any of your readers identify it?—E. H.

THE TEA ROLLER PATENT CASE:
JACKSON VS. BROWN.

79, Farringdon Road, London, E. C.

SIR,—I have seen a copy of your issue of Feb. 18th, giving an account of this case, and wherein Mr. John Brown, the defendant, is reported to have denied having ever had any conversation with me, or that he had ever spoken to me about Tea Machinery.

This somewhat surprises me; as I spent the afternoon of Wednesday, the 8th February 1888, in his company at Bolgravia, in the Dimbala district, on which occasion were present, Messrs. Mackie, Sinclair, and the late Mr. John McLeod, when we talked about Tea Machinery among other subjects.

Thanking you in anticipation for kindly inserting this letter, I am, yours truly,

JAMES B. DALGARNO.

MR. P. D. G. CLARK AND THE EXPEDI-
TION TO PERU.

R. B. Gardens, Peradeniya, March 24th.

SIR,—With regard to the discussion now engaged in by your correspondent in your issue of 22nd instant, relative to the position held by me in the late expedition to Peru, I shall feel obliged by your publishing the enclosed extract from a memorandum of instructions received by me from the Peruvian Corporation, prior to my leaving England for Peru.—I am, yours faithfully,

P. D. G. CLARK.

(Extract alluded to.)

It is desired you should accompany this expedition, or undertake independent expeditions, and report generally on the products of the country traversed, and of the lands in the vicinity of any property selected for the purposes above mentioned, or which you may think it desirable for the Corporation to select, with a view to future development. This investigation should be directed to the actual economic products of the country, and the capability of lands for cultivation, specifying what class of cultivation would best tend to its development. You should also deal with the climatic conditions of the different localities, the labour available, means of transport, and similar subjects. Such for example as the industry of rice growing, cacao planting, cane growing, vanilla growing, rubber planting, etc. Information of a general nature as to the mode of life in the interior, the existing settlements and trading stations, and the flora of the different districts would be of great use in enabling the Corporation to determine the location of lands and the uses to which such land can properly be put.

Your official reports and communications had better be addressed to me here or to the Secretary.

(Signed) GERALD A. ALLARD, Manager.

66, Old Broad Street, London. 27th April 1891.

[The above certainly justifies Mr. Clark's independent action; but we can scarcely believe that a copy of this resolution was supplied to the Commissioners.—ED. T. A.]

MR. J. L. SHAND ON OVERPLUCKED TEA BUSHES.

Gampola, March 28th.

DEAR SIR,—I have been astonished that the local papers, which look after the planting interest, have allowed Mr. J. L. Shand's strictures on Ceylon tea planters, regarding the management of their tea bushes, to pass unchallenged.

Mr. Shand, is in my opinion, a very clever man, but is he an adept in tea planting matters? It is now some 5 or 6 years since Mr. Shand was last in Ceylon; and the management of the tea bush has *very much* altered in the interval: when Mr. Shand left Ceylon tea bushes were pruned every twelve months; now few people prune before the bushes have run 15 months; a good many planters allow them to run 18 months, and instances are known of the bushes having been allowed to run for 2 years. Because the bushes look ragged at the end of 18 months for pruning, is that a proper reason for saying that they are dying out?

When in Ireland amongst the farmers I have heard them speak of some of their cows as "strippers"; now a "stripper" is a cow which is milked straight on end for 2 years, or so, and when in her condition of "stripperhood" only gives about 3rds of the quantity of milk given by her sister-cow; yet a farmer would not say that the "stripper" had deteriorated. She is kept on milking for a certain purpose, and if I am not mistaken, the quality of the milk is above the average, just as the quality of tea plucked from long-run tea bushes is above the average. It is good and right to deery the inflated estimates of tea quantities given out by some people, amongst others your good selves,* and I think, and from the beginning have said, that inflated estimates of quantity are against the interests of Ceylon tea planters; but if it is allowed uncontradicted, to be stated by "An Authority" that the tea planting industry of Ceylon is ephemeral it will be a grievous wrong to Ceylon tea planters. My own opinion is

* Our estimate was, and is, 85 millions, against 80 millions by Messrs. H. Bois and W. W. Mitchell. We deny inflation.—ED. T. A.

that tea is going to be fairly permanent in Ceylon, as the country is essentially a leaf-producing land. Look at our eternal patanas! The *raison d'être* for this letter is that Ceylon planting interests exist to a great extent on borrowed British capital.—Yours faithfully, J. F. R.

[It is for Ceylon planters to deal with Mr. Shand's statements. We have endorsed neither his statements nor his low estimate.—ED. T. A.]

PUSHING TEA IN AMERICA: MR. LIPTON TO THE RESCUE.

Nuwara Eliya, April 6th.

DEAR SIR,—The still further curtailment of tea prices likely to take place in the near future, together with the fact of Mr. Lipton's presence in Ceylon, appear to me, to make it advisable at least to attempt to come to some understanding with him in regard to pushing Ceylon teas in America, rather than go on in the present one-horse fashion, which will not, I believe, appreciably affect the Ceylon tea crop within the next 20 years. There is no use of going back to the question of the present American company, with its wonderful ways of paying for advertizing, &c. further than to remark that many—very many—of our producers are keenly disappointed with the results of its sales.

It might be well, however, to ask Mr. Lipton to give the public, through your columns, his opinion of its ways of doing business and the probable results. As a dealer of American repute Mr. Lipton's opinion would be valuable and instructive; and it might be well to ask those gentlemen who (when Mr. Elwood May made his *début* as the guiding hand of its destinies) sang its praises so loudly here, and in London, whether one of them has invested a single dollar in the company beyond his original shares, which he could not get rid of.

I believe that the Chicago Exhibition expenditure will be wasted money so far as the Ceylon tea enterprise is concerned, unless we have some means behind it, of placing the article in every city, throughout the length and breadth of America, and at rates that will compete with and out Japanese and other teas now being sold there. I believe Mr. Lipton is the one man to do this, as his wealth is enormous and his influence in America generally, and in Chicago particularly is immense. And Mr. Grinlinton evidently recognised this, when he left a letter asking Mr. Lipton's assistance in Chicago (vide *Observer*). The *Observer* says that Mr. Lipton intends to sell only unblended pure Ceylon tea in the United States; but I conclude this must be a reporter's mistake, as no sane man would adopt this course unless he were prepared to face heavy losses.

I have seen Ceylon tea in America selling for \$1 25 per lb. that could be bought in London at 1s to 1s 2d per lb. wholesale, which means that while the Ceylon planter for all his hard work and estate expenditure, interest on capital, and shipping and selling charges was getting 1s, or say 1s 2d per lb., the retailer was getting for handling the tea about 4s per lb. So there is a big margin for profit, and competition, and for pushing Ceylon teas.

I think it is less than 5 years since Mr. Lipton started as a tea dealer in England, and at present, according to the *Observer* he is selling 7½ million lb. of Ceylon tea per annum (half of 3,000 chests sold weekly); and if this is the case, he is the best friend the colony has in the buying market. And when he starts there he will, I doubt,

not, sell in America one ton for each half chest now being sold.

What does it matter to us whether Lipton sells his tea as Ceylon pure, or mixed with other teas, so long as he is able to place some millions of lb. of our staple annually on a new market.

Does a distiller care whether his whisky is sold pure, or blended by the retailer, so long as he is able to dispose of it at profitable rates? As in whisky so in tea, blending often improves both the kinds used.

There has been a vast amount of nonsense talked about selling pure Ceylon tea unblended, when what we want is a profitable market for it, blended or unblended, and our persistent course of refusing to sell it in America as a blended tea is depriving Ceylon of some millions of customers, who would gladly do business if we could give them a good blend such as can be got in England.

Apologising for trespassing so much far on your space, and trusting the matter may be well ventilated during Mr. Lipton's visit to Ceylon, and that some good may result, I am, &c., L. D.

MR. LIPTON ON THE PUSHING OF CEYLON TEA IN AMERICA.

Dambatenne, Naputale, 11th April.

DEAR SIR,—I have today read "L. D.'s" letter with much interest, and although I have never written letters to the Press regarding my business or intentions, I have much pleasure in responding to the invitation conveyed by your correspondent to place my views with regard to the Tea Trade of America before your readers.

The Ceylon American Tea Co. has certainly a great work before it, and under the able guidance of the Hon. Mr. Grinlinton and his friends ought to be of much service to the planters here. I must, however, say that the method of advertising adopted by the Company has not had the effect of making its establishments known outside a very few people in New York. For instance, last September, I, myself, who am deeply interested in all matters affecting the tea trade, spent several hours in trying to find out where they were located. Of course had I had their advertisement in my pocket I could easily have found their place out. I went to the shop they had been in one year previously and also to a place in Twenty-third Street where I understood they had been carrying on business since. I got several addresses where I was likely to find them, but after all had to give up the search. When this was my experience, you can imagine what it must be for would-be customers who were not sure of the address. No doubt there are hundreds of tradesmen in New York who would be as difficult to find, but for a business to be successful everybody should know of its whereabouts.

Two years ago I had the pleasure of meeting Mr. Grinlinton in Chicago, and of showing him over my slaughtering and packing houses, and I also met him in New York. It does not require me to state the interest he takes in Ceylon, but I cannot refrain from saying here that I never met anyone who was so devoted and anxious for the success of the Ceylon tea trade than is the gentleman who has been unanimously appointed Commissioner to represent the interests of the Ceylon planters at the Chicago Exhibition.

To make a big success of a retail business, it scarcely matters what value you offer unless it be well advertised and conspicuously put before the public. If this is not done the chances are the Company will only continue to be a "one-horse

concern." It would be better for the retail shopkeepers, as well as for the planters, that there should be more competition in the tea trade in America. The more Ceylon tea is advertised and the more shops opened for its sale, the more talk about it would be caused and a greater demand for it created. Personally I would much prefer that there was more opposition in America than there is at the present time.

I hope to be able to make arrangements to start the retail tea business in the United States and Canada early next year. I would have been there as a tea dealer before now, but I do not wish to break up my staff in London in taking over those who have ably helped in making my tea business what it is until I have completed opening my new branches in the United Kingdom. My expectation is that by the end of this year I will have branches in every town of importance in Great Britain from John O'Groat's to Land's End. I have already now thirty retail stores in London alone, and expect by Christmas to have at least fifty. Scotland, I may say, I have finished, and England too, with the exception of a few south-eastern counties, and Ireland all but two or three towns. So that when this work is done I can devote my mind and employ my staff in opening retail tea shops from the Atlantic to the Pacific.

I have already a large provision trade in the U. S. over the whole of the country, to meet the requirements of which I have to kill in the Chicago stock yards several thousand head of hogs daily, but this business meantime is entirely wholesale. When I put my tea before the American public it will be as a retailer. My faith is so strong in the future of America as a field for the sale of British-grown tea that I mean to erect manipulating and distributing warehouses there, the same as I have in London.

From the way tea is handled in America, it is surprising that as much is sold as there is. For instance, I saw last autumn in Chicago at the door of one of the principal grocers in State Street, which is the principal street of the city, tea exposed to all kinds of weather, just as you would see rice or barley at home. When you purchase tea in those shops they put it up in a very careless manner, and in a cheaply got-up bag. I asked about Ceylon tea in some shops, and they said they had never heard of tea from that place, the only kinds you could get, as a rule, being oolongs, Japans, common sorts of green tea, and very inferior China congou. These teas, if ever they had been good, were entirely destroyed by the careless way in which they were treated, in addition to which the prices charged were very excessive. This style of business does not tend to encourage tea drinking. When Americans visit the old country they drink as much tea as the English, and the universal cry is that they cannot get tea with the same flavor at their own homes. I have already regular orders for supplying hotels and families with tea in the United States; for instance the great Armour of Chicago, whose fame is deservedly world-wide, wrote to me some two months ago and said: "I consider both my own house and those of my children are incomplete unless they are well supplied with Lipton's teas. We cannot get such teas anywhere in our country which will give us anything like the same satisfaction."

I have frequently asserted, and I adhere to my formerly expressed intentions, that when I start in the tea trade in America, I shall sell a pure Ceylon tea, of course, in addition to such blends of Ceylon and Indian teas as I may consider advisable.

I notice that "L. D." says he thinks it is five years since I started in the tea trade. I am not, as a fact, three years in the trade until next month. The first week I began to sell tea my sales were over 20 tons, and then not half of my stores had any at all, while now my sales are over 3,000 chests weekly. I regard as one reason of the success of this branch of my business the fact that in offering tea to the public, I blend it on scientific principles to suit the water used in the district wherever each branch may be. For instance the tea I send to Edinburgh is quite distinct from what I sell in Glasgow, while that sold in Newcastle is totally different from the other two, and all widely vary from what I retail in London or Birmingham. The reason for this is that the chemical properties of water vary to an enormous extent, and nothing is more susceptible to the action of different minerals dissolved in water than tea.

What the result of my campaign in America will be has got to be proved, but one thing I do know, whether I am successful or not the consuming public will know what I am offering to sell, and where my stores are, and they will certainly get better value than what they are getting now.

Ceylon tea has a flavor which is not to be equalled, let alone beaten by any of its rivals, and if once the American public "catches on" to this tea, there will be no limit to the demand, provided the present high standard of excellence is maintained.

When I leave my estates I shall go, via Japan, to Chicago, where I hope to have the gratification of meeting Mr. Grinlinton, and if I can be of any service to the Ceylon tea planters through him it will certainly give me very great pleasure.—Yours faithfully,
T. J. LIPTON.

THE INTRODUCTION OF CINCHONA INTO THE EASTERN WORLD.—With reference to the article we quote from the *Chemist and Druggist*, we may say that Mr. Ross was certainly in error in attributing to Mr. Clements Markham the credit of first introducing the cinchona plants into the eastern world. Had Mr. Ross said "into British India and Ceylon" he would have been perfectly correct; and we are rather surprised that Mr. Markham in the course of the discussion did not indicate that to a German botanist employed by the Government of Netherlands India belongs the credit of first introducing the fever plants into the eastern world. We have a very vivid recollection of quoting in 1851, paragraphs translated from the Dutch papers published in Java announcing the arrival of a supply of *kina* plants, and wondering at first what the queer word could mean. It is very true that the species introduced by Hasskarl were not the best; but the same may be said of those which Markham brought to British India and Ceylon in 1860. Some of the crown barks were very good, but all were surpassed by *C. ledgeriana*, a quantity of the seed of which Mr. Ledger sold to the Dutch Government and this plant has so flourished in Java, that the Dutch Colony is likely to be the chief source of cinchona bark for the world. We well recollect the enthusiasm which prevailed and the fortunes which were anticipated as we quoted Mr. Moon's reports of barks which yielded 10, 11 and 13 per cent of quinine. These were special trees, however, and the general average of Java bark now runs from 4 to 7 per cent. Even so, over-production has rendered the enterprise a blessing to the world without a compensating reward to the planters.

CINCHONA IN JAVA.

The gentleman who has kindly translated the following report for us remarks correctly enough that "Cinchona looks as poorly in Java as it does here nearly." Of course the Java bark has the advantage of being richer in quinine:—
Soekaboemi Agriontural Union, Soekaboemi, Java.
Feb. 26th, 1892.

Gentlemen,—In presenting the fourth yearly statistics of the Java factory cinchona bark harvest, we have the honour to offer the following remarks:—

The statement has been delayed by the commission (consisting of two of our members Messrs. O. van Vloten and A. Masfink) who kindly undertook its preparation for the purpose of making it more complete than it has hitherto been, for which we consider that our best thanks are due to these gentlemen. The remarks obtained by them are as follows:—

	Kilograms of bark.	Kilograms of Sulphate of Quinine.
That in 1891 the actual harvest has been	3,479,883	= 152,670
That in 1892 at the present price of the unit there will be harvested	3,117,701	= 144,154
That in case of a rise in the price of the unit say 8 or 9 ct. there will be harvested	3,512,144	= 150,729

On the above we beg to remark:

1st. That this statement virtually includes every existing cinchona plantation, so that the statistics are more complete than they have previously ever been.

2nd. That the statement shows what the factory bark harvested is and is likely to be and does not refer to pharmaceutical bark.

3rd. It is satisfactory to perceive from these statistics that there is likely to be 18,516 kilograms of sulphate of Quinine less harvested in 1892 than was harvested in 1891.

4th. True it is shown that in the event of a rise in the price of the unit, the quantity harvested in 1892 may go up to nearly the same as in 1891, but according to more carefully instituted inquiries, such increase can only be effected by anticipating the harvests of following years.

5th. We think it well to point out that it is of the greatest importance, for the stability of cinchona market, that cinchona planters should send as regularly as possible similar quantities of bark to be put up at each public sale: as experience has proved that large quantities thrown irregularly into the market speedily cause alarm in Amsterdam, and it would much conduce to the interest of planters if importers were more prompt in withdrawing bark, when remunerative prices are not offered.—On account of the directors, G. MUNDT, President, and D. BURGER, Hony. Secretary.

Translated for the *Ceylon Observer* by J. D. Y., 9th April 1892.

The German Government have made arrangements with Apotheker Finselback, late assistant in the botanical laboratory of the Geneva University, to proceed to the Australian Colonies on a scientific tour of investigation of the medicinal and economic plants of that part of the world. Herr Finselback, who is timed to leave Bremerhaven for the Antipodes on April 13th, will devote particular attention to the northern portions of Queensland, making the Carpentaria country the chief seat of his labours. He is not tied to time, however, and, after looking through the Northern Territory of South Australia, he will in all probability pay a visit to British and German New Guinea and the Solomon Islands.—*Colonies and India.*

DR. TRIMEN'S REPORT ON THE
ROYAL BOTANIC GARDENS.

Dr. Trimen's reports are always full of interesting information regarding the valuable institutions under his care and the plants cultivated in them or distributed from them. On this occasion fresh interest attaches to the report for 1891, just issued, on account of the descriptions given of the kindred institutions in the Straits and Java. All who have visited the Buitenzorg Gardens and the Library, Museum and other accessories of the Gardens will feel that the truly imperial liberality of the Dutch Government deserves all the praise which the eminent Ceylon botanist bestows on the institutions of which Dr. Treub is the very efficient head. The publication which Dr. Trimen mentions under the title of "Teijsmannia" perpetuates the name of a previous able Director of the Buitenzorg Gardens.—If we have it not already in Ceylon, we cannot doubt that Dr. Trimen will at once take measures to introduce and naturalize the tree known botanically as *Eusideroxylon*, the hard wood of which is never attacked by termites. The pepper so valued in medicine known as cubobs seems already to have been successfully introduced into Peradeniya, and no doubt plants will be available a few years hence.—The tank which has been formed at Peradeniya and which enables water plants to be grown in snok pots is a great improvement, as well as the substitution of the scythe for the grass knife in the treatment of portions of lawns, which the mowing machines cannot effectually deal with. The prolonged wet had acted deleteriously on giant bamboos and young palmyra plants. The palmyra is essentially a palm of the dry zone; but we are familiar with some fine specimens close to the seashore at Colombo. On this occasion, as on all others, we would impress on the Government and the members of the Forest Department the duty of extending the cultivation of this useful palm in the northern and eastern portions of the island. As Dr. Trimen shows, valuable fibre is now added to the excellent timber, fruit and saccharine juice which the tree yields. There was a considerable increase of visitors to Peradeniya and Hakgala during 1891, including the heir to the Russian throne, who planted an iron wood tree at Peradeniya opposite to a bo-tree which had been previously planted by the heir to the British throne. The year to which the report refers was exceptionally wet in the south-west and central regions of Ceylon, the rainfall at Peradeniya showing excesses of 34 inches of rain and 63 rainy days over the averages. The figures were 117.71 inches, against an average of 84.99, and 212 rainy days against an average of 149. Of the rain 27.73 inches fell in October. Similar weather, varied by drought and frost, prevailed at Hakgala, to the great detriment of walks and the destruction of plants. Mr. Nock complains of the dilatoriness of the Public Works Department in regard to a reservoir to provide against drought, and states that he is using brick labels to distinguish the plants grown at Hakgala after the example set at Peradeniya. It is interesting to learn that in the mountain gardens a quantity of cowslips and oxlips flowered amongst the ferns in February. Plums of superior kinds grafted on common stocks and good kinds introduced from Japan promise to be very successful at Hakgala, whence they can be distributed to the gardens of planters and others. The American blackberry also promises to be a success. The same cannot yet be said of cherries and raspberries. It is encouraging to learn that some

of the conifers in the gardens have begun to yield good seeds, for deodar seeds from the Himalayas have, we believe, uniformly failed to germinate in Ceylon. What is said by Mr. Nock about the roots of *Acacia decurrens* shows that this wattle and its congeners ought not to be grown amongst or even near other plants. The tree and its roots and root shoots simply monopolize the soil. *Cupressus macrocarpa* is a success at Hakgala. The more the pity that plants of this tree and of *frenela*, *pinus*, &c., which had been grown successfully on the patnas were destroyed by a fire supposed to have been wilfully kindled. The putting out of plants on the patnas goes on. Mr. Nock is justifiably enthusiastic about the effect of a bed of phloxes of thirteen different colours. He dwells on the necessity of manure and states that he has opened a permanent limekiln. Two of his cattle were killed by a leopard. The weather at Hakgala, it will be seen, was abnormal. The minimum temperature on the grass registered five times below 40° and nineteen times below 50° in January. On the 30th of that month the frost was very severe at Sita Eliya, more native plants having been blackened by it than Mr. Nock had ever observed before. Severe drought and heavy rainfall were equally trying. The total rainfall for the year was 118.65 which fell on 205 days, being 33.51 inches above the average fall of seven years, but only one above the average of rainy days, a curious result, surely. The rainfall in October was 22.85 inches. The temperature of the air was—maximum 73°, minimum 41.5°. Highest in the sun's rays 148.8°, lowest on the grass 38.8° on March 1st.—The rainfall of the tropical gardens at Hensratoda is given for the first time: 120.17 inches on 172 days, 22.51 falling in October. Dr. Trimen laments the paucity of visitors to these gardens, which we believe is largely due to inconvenient railway arrangements. There is a favourable report of the growth of trees and plants in the Anuradhapura gardens, in which, however, the people intended to be benefited appear to take not the slightest interest. The few purchasers of plants are all Tamils. What is wanted to waken up the inert Sinhalese is the extension of the railway. A like good account is given of the Badulla gardens where conifers specially flourish, but nothing is said of how the Uva natives appreciate the plants grown for them. The year was excessively wet, 142.48 inches of rain having fallen, of which 87.74 came in the last quarter, October showing no less than 41.67 inches. Badulla has been visited by heavy rainstorms in 1892 also.—Dr. Trimen's notes on economic plants are, as usual, valuable and suggestive. He rightly attributes the defective quality of Ceylon tea in 1891 to the excessive rainfall. From his report alone we learn that *helopeltis* has done little damage on lowcountry estates. In India and Java, the insect is a formidable pest. Dr. Trimen is of opinion as a result of his visit to Java that the cultivation of Liberian coffee was too hastily abandoned in Ceylon. There were two reasons: the fungus was prevalent and injurious in proportion to the size of the leaves, and the proportion of skin to fruit was great and pulping very difficult. Prices also were not so good as they now are. As to cinchona, the real advantage of Java is the possession of the high quality species, *C. ledgeriana*. Dr. Trimen remains of opinion that the high prices paid for Ceylon cacao is due simply to the superior treatment of the beans by our planters. Government are trying experiments with indiarubber trees, and Dr. Trimen gives an interesting account of the cultivation and preparation of gambier in Singapore. On this subject Mr. Ridley has prepared a most exhaustive

paper which we have marked for insertion in the *Tropical Agriculturist*. The survival of a calumba root plant at Peradeniya, supposed to have been dead years ago, is a curious event to record. The introduction of a new and superior kind of mabo-gany tree is also interesting. Altogether the Botanic Gardens report for 1891, of which we give the larger portion as a Supplement, will be found interesting and suggestive reading. We shall next look for the Flora of Ceylon, copies of the first volume of which Dr. Trimen may be able to bring to the colony when he returns from his mission to the Imperial Institute.

CEYLON TEA FUND.

Minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held at Kandy on Friday, the 8th day of April 1892, at half past nine o'clock in the morning (9.30 a.m.).

Present:—Messrs. Giles F. Walker (Chairman) Planters' Association of Ceylon), John Aymer (Honorary Secretary Dolohage and Yakkessa Association), J. Stuart (Chairman, Dolohage and Yakkessa Association), R. S. Duff Tytler (Sabaragamawa), J. Anderson (Kandy and Matale West), A. E. Wright (Muskeliya), W. Cross Buchanan (Dinbula), J. H. Staroy, Kandy, A. Philip (Secretary to the Planters' Association of Ceylon), Kaady.

The notice calling the meeting was read.

The minutes of proceedings of a meeting of the Standing Committee held at Kandy on Monday, the 4th January 1892, were taken as read and were confirmed.

Read letter from the Silver Kaady, Ceylon Tea Company, Limited, Manchester.

Read letter from Mr. Robt. N. Aoley, Wattagana.

Read letter from Mr. Eric S. Anderson, W. Chas. Witham and Hugh B. Roberts.

Read letter from Mr. Joseph Fraser.

Read letter from Mr. C. J. Donald, the New Oriental Bank Estate Company, Limited, Colombo. Resolved:—"That while the Standing Committee of the Tea Fund cannot see its way to publishing the information asked for, there is no objection to the Agent of the Company or any one appointed for the purpose of obtaining the desired data personally at the Secretary's office."

Submitted letter from Messrs. J. M. Robertson & Co. Resolved:—"That referring to previous correspondence Messrs. J. M. Robertson & Co. he informed that the subscriptions they may send into the Tea Fund will be devoted as far as possible to the objects they may specify in accordance with their wishes."

Read letter from Mr. E. Bowden Smith. Resolved:—"That Mr. E. Bowden Smith's request be complied with."

CEYLON TEA KIOSK.

Read letter from the Manager Ceylon Tea Kiosk. Submitted accounts for additional works in connection with the Tea Kiosk at Colombo. Resolved:—"That subject to the amount already voted with interest thereon not being exceeded the additional claim be referred to the Sub-Committee appointed for the purpose of establishing a Tea Kiosk at Colombo."

Read letter from the Chairman, Ceylon Chamber of Commerce.

ALLOWANCE TO CHICAGO EXHIBITION COMMISSIONER.

Read letter from the Colonial Secretary to the Chairman and his reply relative to the proposed allowance to be made to Mr. Grinlinton as Commissioner for Ceylon at the Chicago Exhibition. Resolved:—"That the reply by the Chairman of the Planters' Association be approved of by the standing Committee of the Tea Fund."

DEPOSIT OF CHICAGO EXHIBITION FUND SUBSCRIPTIONS IN THE COLONIAL TREASURY.

Read letters from the Colonial Secretary and from Mr. J. J. Grinlinton. Resolved:—"That the sum of

Rs 5000 be paid into the Colonial Treasury to credit of the Chicago Exhibition Fund, and that the question of depositing the Chicago Exhibition Fund Subscriptions in the Colonial Treasury be brought up again at next meeting of the Standing Committee."

CHICAGO EXHIBITION.

Read letters from the Colonial Secretary and from Mr. J. J. Grinlinton.

Read letter from Mr. H. D. Deane on the subject of exhibiting green teas at the Chicago Exhibition. Resolved:—"That the question be taken into consideration."

CEYLON TEA IN GERMANY.

Submitted letter to Mr. Schrader, transmitting copy of resolution of the Standing Committee of the Tea Fund as regards the subsidy of Ceylon teas follows:—"That the Standing Committee of the Ceylon Tea Fund do grant to Mr. Schrader 5,000 lb. of Ceylon tea in two instalments for free distribution in Germany the Committee understanding that Mr. Schrader is prepared to purchase an equal quantity of Ceylon tea on his own account." Notified that up to date no acknowledgment and reply had been received from Mr. Schrader.

CEYLON TEA IN VIENNA, PRAGUE, KARLSBAD &c.

Read letter from the Directors of the Imperial Royal Austrian Commercial Museum stating that they are unable to state which qualities of Ceylon tea would sell best at Vienna but suggesting that a collection should be sent embracing all the qualities of Ceylon tea which they would submit to Vienna importers, who will then single out the suitable qualities. Resolved:—"That the Ceylon Tea Company Limited be requested to purchase and forward to the Directors of the Imperial Royal Austrian Commercial Museum, the following samples of Ceylon tea, viz. 5. 2 lb. packets of each quality viz.: XX. X. Y. Z., as made up by the Ceylon Tea Company."

CEYLON TEA IN RUSSIA.

Submitted letter to Mr. Rogivue forwarding to him the following resolution passed by the Standing Committee of the Tea Fund, viz.:—"That, in acknowledging Mr. Rogivue's letter, he be informed that the Standing Committee of the Tea Fund trusts to receive further accounts showing an increasing sale of Ceylon tea in Russia during the present year when the Committee will be prepared to consider what further assistance they may be in a position to give Mr. Rogivue at the next fair at Nijoi Novgorod."

CEYLON TEA IN SWITZERLAND AND AUSTRIA.

Read letter from Messrs. Whittall & Co. intimating (I) that effect had, as requested, been given by them to the execution of the instructions given in connection with the following resolution, viz.:—"That a grant of 500 lb. of Ceylon Tea delivered free at Trieste duty paid be made to Mr. C. Oswald for gratis distribution in Vienna by Mr. Weiner," and (II) that the tea will be shipped by first opportunity.

CEYLON TEA IN CANAUA

Read letter from Mr. J. Anderson with enclosures.

ADVERTISING CEYLON TEA.

Read letter from Mr. K. Mueandrow making suggestions regarding an effective advertisement of Ceylon Tea.

MAKING KNOWN CEYLON TEA BY LECTURES AND BY PHOTOGRAPHS.

Read letter from Mr. W. Herbert Jones, F.R.C.I., offering to further thoroughly advertise Ceylon tea in Great Britain by lectures on Ceylon accompanied by photographic views. Resolved:—"That a copy of the letter be forwarded to Mr. John Ferguson of Colombo in London for his opinion; and that Messrs Sken & Co. be requested to state on what terms they would supply a set of photographs as indicated."

CEYLON TEA IN HUNGARY, ROMANIA, BULGARIA AND SERBIA.

Read letter from Messrs. Walker Brothers transmitting a letter from Mr. Hugo Graepel, Budapest. Resolved:—"That a grant of Ceylon tea in $\frac{1}{2}$ lb. packets will be made to Mr. Graepel for free distribution in Hungary, Roumania, Bulgaria and Serbia on his furnishing information as to the port to which the tea should be sent and by what line of steamer."

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From S. Figgis & Co.'s Fortnightly Price Current, London, April 7th, 1892.)

ROYAL BOTANIC GARDENS.

REPORT OF THE DIRECTOR FOR 1891.

I.—MOVEMENTS OF THE STAFF.

THE Director, by permission of His Excellency the Governor, visited in the early part of the year the Botanic Gardens at Singapore and at Buitenzorg (Java), being absent on that duty from February 27 to April 5. I had long desired to have an opportunity of examining the two principal botanical establishments in Malaya, and especially the great scientific institution kept up by the Government of the Dutch Indies. During this short visit I acquired much new information, and made many useful additions to our collections, as will be seen in this report; and I may add here a few notes as to the character of the two Gardens in general.

There is little to be said about that at Singapore, which is situated close to the town, and has to fulfil somewhat of the part of a public park as well as of a scientific garden. Both aspects are well carried out: there is more ornamental gardening than we are accustomed to see in Ceylon, the turf is well kept, and the flower-beds very neat for a tropical climate, whilst there is a large and valuable collection of rare Malayan plants. The ground for the experimental culture of economic plants is separated by some distance from the Garden itself, which is a very good arrangement. The Director has under him a European Head Gardener and two or three good native assistants; and has also charge of branch gardens, each under a trained English gardener, at Penang and Malacca. The Herbarium and Library are being rapidly extended and improved.

The Dutch botanical establishment at Buitenzorg is of a different character from this or any English one, not even excepting Kew, and is maintained entirely on a scientific basis. The Director has the control of all the six departments into which the institution is divided, as follows:—1, the Herbarium, Library, and Museum; 2, the Botanical Laboratory; 3, the Experimental Garden and Laboratory for Agricultural Chemistry; 4, the Pharmacological Laboratory; 5, the Botanic Gardens; 6, the Photographic Institution. Each of these departments is under the immediate management of a highly trained scientific or technical chief from Holland, and most of these have also an assistant. There is thus a very large staff of Europeans. The Laboratories, Library, &c., are completely stocked, and kept fully up to the time, and everything is provided for close investigation and original research in all branches of botanical study. Many students are thus attracted from Europe, and the Laboratories afford accommodation for a considerable number of workers. A valuable serial publication, the "Annales du Jard. Buitenzorg," is issued at intervals, devoted to scientific botany, and another one, "Teijsmannia," occupied with economic and garden subjects.

The Botanic Gardens themselves at Buitenzorg occupy between 60 and 70 acres, at an elevation of about 800 ft., with a fine soil and abundant water, and are well protected by a high iron railing and a barbed wire fence. Nearly the whole is occupied by a classified arboretum, each Natural Order being isolated by a road or path. The collection is extremely rich, and every species is elaborately labelled with upright labels made of the very hard wood of *Eusideroxylon*, which is never attacked by termites. The whole is now much too crowded, and cannot be said to be of much beauty, but is of course extremely convenient for scientific study. Connected with Buitenzorg is a small Hill-garden at Tjibodas, 4,700 ft., also under a European superintendent, where is also a house for the Director and a laboratory and accommodation for four students.

The Experimental Garden (Cultuur-tuin) is about two miles from the main Garden, and is 200 acres in extent, but is not all at present occupied. It is laid out in square plots, each devoted to one product; large labels at each corner give the name, date of sowing or planting, and other information. Here are very many plants of great interest. Though a large distribution of seeds and plants is made to planters and others, no charge is made for anything.

On the whole, I was filled with surprise and admiration at the completeness of Buitenzorg as a centre for botanical work ; the only weak side seemed to be the Herbarium, which is by no means kept up on a par with the rest of the means of study.

The Head Gardener, Mr. Clark, went on leave to England on February 11, and had not returned at the end of the year.* For the greater part of this time he has been travelling, for the Peruvian Corporation, in the Andes, whence he has sent (through Kew) a few seeds of useful and ornamental plants for cultivation here.

Mr. H. M. Alwis, the Clerk and Foreman at Hakgala Garden, left the Department in July, after a very satisfactory service of nine years, to take charge of the Victoria Park Gardens in Colombo under the Municipality. His place has been filled by the appointment of Mr. M. G. Percera, from the Forest Department, who had previously served under Mr. Nock at Hakgala, and given satisfaction.

2.—PÉRÁDENIYA GARDEN.

Roads and Paths.—The almost constant rain throughout the year has rendered necessary a continuous attention to all the drives and footpaths, so that no extensive repairs have been anywhere undertaken. The road round the Palm Crescent in the South Garden was however partly remade, and a portion of the Central Drive, during the dry time at the commencement of the year.

Buildings.—I regret that my efforts to obtain a suitable dwelling for the Head Gardener have been again unsuccessful, and that he will be compelled to still continue to live in the incommodious old store, the demolition of which I have so often urged. I trust it is deferred only. Some repairs to the roof and flooring of the building have been made by the Public Works Department during the year, which have rendered it a little more suitable for a dwelling-house.

The much-needed repairs and alterations to the Director's bungalow are to be taken in hand in 1892 ; the other buildings that now require attention, after the long wet weather, are the Museum, which needs new pipes and guttering, and the houses occupied by the Garden Arachchi and the Draftsman, which both much require repairs to the roofing, &c.

During the year a small dwelling for the second gate-peon was put up in the Garden, and the plant-collector's new house finished. These have both been erected at the cost of the Gardens ; and I may here remark that it is my practice to effect all small repairs in the same way, the Public Works Department being required only to estimate for the larger works beyond our means.

Improvements.—A balance remaining on the vote granted by Government to supplement the sum given by the British Association for conveying water to the Laboratory (see last year's Report), I asked permission to be allowed to employ it in the formation of a small tank and fountain. This was granted, and the work was carried out in June and July. The tank occupies a little open space under the shadow of the largest trees of *Ficus elastica* ; it is circular, with a diameter of 24 ft., and a continuous stream of water flows through it. Its depth, 2 ft. 3 in., allows the growth of water-plants in sunk pots, which we have hitherto had no opportunity of cultivating. The fountain in the centre is supplied by a small pipe, and can only be played to its full height of 18 or 20 ft. when the water-supply to the rest of the Garden is cut off ; otherwise it rises to only about 6 or 8 ft. This change has much improved the appearance of that part of the Garden affected, formerly a damp patch of rank grass where nothing else would grow.

I have introduced the use of the scythe to Pérádeniya during the year. I observed that in Java and the Straits the Malay and Javanese gardeners mowed fairly well, and I now find that after a little practice several of our Tamil and Singhalese men can handle the scythe after a fashion, and produce a better result than with the old grass-knives hitherto used in places where the large and small machines cannot be employed.

Cultivation.—Many of the palms in the grove by the entrance having become with age very tall and lanky, some of the commoner ones have been cut out, and specimens of rarer kinds planted to supply their places.

The young palmyra palms (sown in 1889), intended to form an avenue, have greatly suffered from the prolonged wet ; an endeavour to save them has been made by cutting deep drains on either side.

The collection of ferns in pots kept in one of the old plant-sheds has been improved in appearance by widening the brick stages on which they are placed, and so giving more room for their proper development.

Two or three of the fine clumps of Giant bamboo have died during the year without apparent cause. I think that this species is unable to bear excessive and prolonged wet weather.

The male Coco-de-mer palm (*Lodoicea*) again put out a flower-spike, which came into blossom in September, and continues at the end of the year to open a few flowers at a time successively.

* Returned to duty on February 10, 1892.

Among the plants which flowered during the year for the first time may be noted :—*Saraca declinata*, *Leea sanguinea*, *Passiflora Watsoniana*, *Tristillateia australasica*, *Euadenia eminens*, *Eranthemum velutinum*, *Chlorocodon Whitei*, *Pavetta madagascariensis*, *Ipomœa Briggsii*, *Asystasia flava*, *Gynura sarmentosa*, *Ruellia affinis*, *Arancaria Cookii*, *Euphorbia heterophylla*, *Lagetta tinctoria*, *Carludovica ensiformis*, *Smilax officinalis*, *Aplidium floribundum*, *Æchmea calyculata*; and of Orchids :—*Galeandra Devoniana*, *Epidendrum aloefolium*, *E. Stamfordianum*, *Calanthe Regnierii* and *C. Sanderiana*, *Vanda teres*, *V. Hookeriana*, *Ceologyne cristata*, *Dendrobium Loicci*, *D. lituiflorum*, *D. Cassiope*, *Lælia grandis*, *Cattleya eldorado*, *C. Mendelii*, *Bifrenaria atropurpurea* (?), *Arundina densiflora*, *Dendrochilum filiforme*, *Miltonia Weltoni*, *Cycnoches chlorochilum*, *Rodriguezia fragrans*, *R. candida*, *Oncidium splendidum*, *Platænopsis Esmeralda*, *Plocoglottis* sp., *Cypripedium Haynaldianum*, *C. Sedenii*.

Labelling.—This has been steadily persevered with, a writer being employed throughout the whole year. Most of his work has been writing labels for the plants in pots (several thousands), orchids, aroids, ferns, &c. Nearly all the wooden tallies formerly used have now been supplanted by neat tin labels, black, with the names in white paint.

Race-course Ground.—The forest of weeds covering this was cleared off and burnt early in the year, but by May it had largely grown up again, and a second clearance had to be made. This nearly exhausted the small sum of money at my disposal, and I was unable to make a much-needed third clearance before the end of the year, though the rains caused a heavy growth to again spring up. I regret that my original request was not complied with and a smaller piece reserved, which could have then had more attention given to it, and be constantly kept in order.

Visitors.—The number of foreign visitors and tourists who entered their names in the book kept at the Lodge during the year was 1,792, a considerably large number than hitherto. Most of our visitors come in the early part of the year, especially in February.

On February 13, H. I. H. the Czarewitch of Russia visited the Gardens in company with his Excellency the Governor, and planted a tree as a memorial of his visit. I selected a ná tree (*Mesua ferrea*), and a spot opposite to the bó tree (*Ficus religiosa*) planted by H. R. H. the Prince of Wales in 1875.

Weather.—A very exceptionally wet year has to be recorded, the rainfall having exceeded our average by nearly 34 in., and fallen on 63 days more than the average number. This remarkable period of wet weather set in on March 7, the season up to that date having been of the ordinary dry character of the north-east monsoon season. From March 7 to 17 it rained continuously, and from that date to the end of the year more or less wet weather has been experienced. From April 15 to June 6 only six days passed without rain, the fall in May being 21·30 in., against an average of 7·67. The south-west monsoon wind set in about May 17 here, and blew vigorously for over three months. From June 12 to July 4 there was but a single rainless day, but after that a period rather drier than usual was experienced—that is, with less rain, though with more rainy days—until early in October, when the rain set in with increased persistence. From October 3 to November 16 only three days passed without rain, and the total fall for October reached the unprecedented figure of 27·73, or about 2½ times the average amount. We had a fortnight of dry weather at the end of November, after which heavy rain again set in and continued till the end of the year.

These facts are shown in the subjoined table, where the averages for the past 7–8 years are also given :—

Rainfall at Péradeniya.

	1891.			Average.		
	Rainfall.	Rainy Days.		Rainfall.	Rainy Days.	
January ...	2·66	7	...	1·86	4	} 1884–90
February ...	1·57	5	...	1·43	4	
March ...	10·73	13	...	3·59	8	
April ...	12·73	15	...	9·48	13	
May ...	21·30	29	...	7·67	12	
June ...	8·72	23	...	9·94	20	
July ...	4·36	21	...	7·66	16	} 1883–90
August ...	5·02	17	...	6·62	15	
September ...	2·74	19	...	7·83	14	
October ...	27·73	29	...	11·21	18	
November...	6·00	12	...	9·96	17	
December...	14·15	22	...	7·92	11	
Year ...	117·71	212		84·99	149	1884–90

The heaviest fall in any recorded twenty-four hours was 4·85 in. on October 19–20.

3.—HAKGALA GARDEN.

Such improvements as our votes will allow have been effected during the year, and the Garden continues gradually to advance under the assiduous care of the Superintendent, Mr. Nock. I am gratified to know that an increased vote for upkeep is to be granted for the coming year, which will render progress somewhat more rapid.

Another portion of the old drive has been taken in hand and finished off. This was the worst remaining piece, 130 yards in length, very uneven and irregular, and with a gradient in one part of as much as 1 in 9. By altering the curves and adopting a new trace a uniform gradient of 1 in 15 has been obtained, and the banks being cut back and sloped the road has been greatly improved in appearance and utility.

A second propagating pit has been constructed during the year. It forms a sunk span-roofed house, 36 ft. long by 12 ft. wide, the details of which are given below. This is a great aid to garden work and the maintenance of a stock of plants.

I regret to have to report that much less progress has been made by the Public Works Department with the reservoir than might have been expected. The work of excavation was not even commenced till May 8, and it was not till July that the foundations of the walls were laid. Then, at the end of September, it was discovered that the sum voted for the whole work was exhausted, though little more than half of it was done. Work was not commenced again till December 16 (with a supplementary vote), and as little could be done during the wet weather at the close of that month, the end of the year sees us still without any provision against the probable droughts of March and April.

I have made a commencement towards labelling the more prominent trees and other plants on a similar plan to that in use at Pérádeniya, and about 300 brick labels have been painted and put in position. I hope to continue this work during the coming year.

A permanent shelter for carriages and horses, in place of the shabby and dilapidated structure at present used, is one of the most pressing requirements at this Garden.

The following details are extracted from the Superintendent's Report for the year :—

One of the principal pieces of work during the year has been the construction of a span-roofed pit for the propagation and growth of young plants. It is 36 ft. long and 12 ft. wide. From the ridge to the floor it is 7 ft. 6 in. The walls up to 12 in. above surface-level are made of split stones. The uprights for the side lights, which are 18 in. deep, are fitted on to this, and the wall plates on top of this support the roof. Three iron tie-rods, three quarters of an inch in diameter, screwed to the ridge and wall plates, strengthen the roof and keep it in place. Four side lights on each side are made to open with small hand levers to admit air, and three small lights on each side of the roof for top air. The pit is entered by a flight of four steps on each side. These steps are 4 ft. 6 in. wide, the tread 12 in., and the rise of each step 10 in. The path, which is 3 ft. below the surface of the ground, runs along the centre, and is 3 ft. wide. The stages which are made of 2-in. planks are supported by brick pillars, 9 in. square, and are 3 ft. 6 in. wide. This, with the 8-in. margin of wall all round, gives us about 250 superficial feet of stage-room for plants. The roof is glazed with ordinary glass. The stages were put in, the woodwork well painted, and all made ready to receive plants by the end of September. All that remains now to complete it is a small coping for the ridge and guttering round the eaves.

Fernery.—Beyond cutting down the undergrowth for a space of twenty-four yards wide on the upper side, fixing orchids on to the stems of the large trees, and thinning out and pruning the jungle trees, nothing but the ordinary weeding, cleaning, and replanting was done in the fernery. During the high winds in June a tree, which afforded shade to the large clump of *Adiantum cuneatum*, was blown down, and the plants here suffered a good deal from exposure. With the exception of about six weeks during the drought the plants generally here have done well, and continued to be attractive to visitors. A quantity of cowslips and oxlips flowered very well among the ferns in February.

Plant Sheds and Nurseries.—The usual stock of plants, trees, and shrubs has been kept up, both for distribution and for the upkeep of the Garden. I regret, however, to report that, owing to the severe drought at one time and continued heavy falls of rain at other times, several batches of cuttings have failed to strike, and many succulent plants were killed completely.

A large number of the grafts which were worked on to stocks of the common plum in November, 1890, united well, and a considerable quantity of them have been distributed. In consequence of the fine bright weather in November the grafting this year was delayed till December, when 190 scions of various kinds of plums were grafted on to common stocks.

Some of the conifers in the Garden are now beginning to produce good seeds. These have been collected, and a part sown in the nursery, and some have been sold.

There were 1,024 pans of seeds sown and 46,550 seedling plants pricked out or transplanted, 60,050 cuttings of various sorts were put in the nursery or propagating house, and 4,844 plants were potted.

Borders, Shrubberies, &c.—Our manure supply is so limited that we were unable to give so liberal a dressing as the soil required.

39,130 plants of ornamental trees and shrubs and general garden plants and annuals were set out during the year in the borders, beds, and shrubberies.

A new border, 66 ft. long, was formed near the carriage shed and planted with herbaceous plants—ribbon-border fashion. A stone drain of the same length, to carry off the water, and one side to support this border, was made here on the side next the drive. Another new border, 111 ft. long, was made near the large

Cupressus tree at the top corner of the herbaceous garden. Stone edging was laid along the side next the path, and over this was planted *Sedum stoloniferum*, and the border was planted with mixed plants.

Considerable improvement was made round the summer arbour. The floor of this was raised 3 in. and a layer of gravel spread on the surface. In front and around the building the land was made even and turfed. The little shrubbery at the back was overrun with roots of *Acacia decurrens*, which had choked out nearly all other plants, and a number of *Leptospermum scoparioides* plants have now been planted this year, in the hope that they will hold out against the *Acacia* roots, as they are very hardy and usually grow fairly well in poor soil.

Two retaining walls have been built to support the new borders running along the lower side of the portion of drive reconstructed this year. The larger measures 168 ft. long with an average height of 4 ft., and the other is 36 ft. long with an average depth of 2½ ft. A large amount of filling in was required to make these borders. The borders have been planted with a large variety of roses, small shrubs, herbaceous plants, and showy annuals.

In the space of ground between the nursery and the rubbish yard, large holes were got out 20 ft. apart, and prepared for growing specimens of trees and large shrubs. Eighty-two assorted plants were planted out in them.

A large flight of steps made of dressed stones were laid down the long bank below the flower garden. This makes a very convenient and short way to reach the new pits, the anemometer and nurseries, and saves much time. The steps are 23 in. number, and 4 ft. wide.

In August the old pond was cleared of growing weeds and of leaves and stalks, and the silt from the two inlets was removed.

Plants of *Cupressus macrocarpa* were planted on the bank near entrance gates at equal distances of 12 ft. apart, and 12 ft. from the edge of the drive. Those planted last year on the opposite side are making good growth.

170 English oak plants and 54 plants of various *Acacias* were set out on the patana near the cooly lines, and 105 plants of several varieties of *Eucalyptus* on either side of the bridle-path leading down to Gorindakela.

New turf verges, measuring 373 running yards, 12 in. wide, were laid down along the sides of the drive and paths, and 220 square yards of turf on banks by new flight of steps, and around the summer arbour.

It is with much regret that I have to report the loss, by fire, of nearly all the young trees of *Junipers*, *Cupressus*, *Frenela*, *Pinus*, &c., which were growing so nicely on the patana above the entrance gates. The fire occurred on April 2 during my absence on a visit to Pérádeniya. The fire originated near the public road, and was evidently lighted by some one passing by, but all efforts to find out who did it failed. This loss is most annoying, as the plants were doing well, and some of them were fully 9 ft. high. We had been unable, for want of labour, to do more than clean occasionally round the collar of each plant, and the patana grass had grown so thick between them, that the fire, when once alight, spread rapidly, and it was not discovered until it was too late to put it out.

During the high winds in June a considerable number of trees were blown down and destroyed. The cold damp weather in the following month, assisted by the strong gusts of wind twisting and shaking about soft and tender plants, killed out more plants than is usual for these months.

Flower Garden.—No alteration of any importance was made in the flower garden. The beds and borders were kept supplied with the usual showy garden plants, and were maintained in good order all through the year. I may mention one bed which was very attractive. It was planted with mixed varieties of *Phlox Drummondii* (of Messrs. Sutton & Sons' strain) and edged with *Antemaria margaritacea*. None of the *Phlox* plants grew higher than 9 in., and formed one compact mass of thirteen distinct colours, and they remained in full bloom for several months.

Rose Garden.—A few new varieties were added during the year, and the plants on the whole have done well. There were some very fine blooms out during the month of March. I was able to stage forty varieties at the Nuwara Eliya Show at the end of that month. The plants were all pruned well back in the middle of January, in order to get them to come in for the Show. Experience has proved that from nine to ten weeks is about the time to allow, in this locality, from the time of pruning till they are in full bloom. The treatment the plants received was the same as last year, with the addition that they were supplied liberally with liquid manure after the flower buds began to show. Great difficulty was experienced this year in getting rose cuttings to strike, and two fine batches were complete failures, owing in a great measure to the severe drought.

Herbaceous Garden.—In March, 232 supplies and additions were planted out in the beds. As a quantity of plants had grown too large for the beds, and a considerable number of the weaker and tender sorts were killed out by the drought, it became necessary to re-arrange the whole garden. This was done in November. All the beds were dug up for a depth of 18 in., and roots and rough stones removed. The beds were heavily manured and filled up with old potting soil and decayed matter from the rubbish yard. Fifty-two cart loads of manure and twenty-nine cart loads of the above-named soil, besides a large quantity of burnt earth and ashes, were used in this work. The plants were all replanted in their Natural Orders as before. Many plants of interest flowered during the year. A fine plant of the "tree daisy" flowered profusely, and continued in bloom for many months.

Manure Supply.—Manure is a great necessity in a Garden like this where the soil is naturally poor. The want of a good supply is more and more felt, and without which it is impossible to do justice to the plants. We have received sixty-five cartloads from the coach shed at the foot of the Garden, the coach proprietor kindly allowing us to have all the manure made there, for the use of the shed which was built by the garden coolies. The only other manure we get is what is made by the five bullocks belonging to the Garden and that made by my own cattle and pigs. Considering the importance of this matter, and the fact that there is a large acreage of Government patana land pasturage in the vicinity of the Garden, I would respectfully suggest the advisability of the purchase of, say, at least half a dozen breeding cows. These could be kept at little cost, and with the young ones they would produce would always be worth the money spent on them. The Garden would thus receive an increasing supply of valuable manure. Manure is readily sold here for two rupees per load, and considering the first cost of half a dozen cows would not be more than one hundred and twenty rupees. They would more than pay this off in the first year.

Cattle Disease.—At the beginning of the year foot-and-mouth disease was very bad in this locality. The garden bulls and most of the other cattle here suffered with it. They were dressed with Jey's disinfectant, and all recovered in about ten days. There were no cases this year of the murrain, which was so prevalent in this district last year.

Two of the most promising young bulls in my herd have been killed by a large leopard, one in April and the other in October. The animal had caused great destruction among the cattle in this neighbourhood for some time previously. We have not yet succeeded in trapping the leopard, though he has been seen in and about the Garden several times since.

Lime Kiln.—A permanent lime kiln was built in February on a site near the lime-stone rock, a few hundred yards below the cool lines. This was built at the expense of the Public Works Department on the understanding that lime be supplied them for the restoration of the reservoir at the price it costs us to burn. This was of course agreed to, and we can now burn lime for the Garden use at any time.

Water Supply.—We have this year again been very short of water, and during the long drought in July, August, and September, a good deal of labour was spent in carrying it, especially for three weeks in September, when from 3,000 to 6,000 gallons were used daily, and the greater part of this had to be carried from the pond in the lower part of the Garden, all the little streams above the Garden having completely dried up.

Visitors.—The number of visitors during the year was 1,519, being an increase of exactly 200 over that of last year. The greatest number in any one month was 206 in December, against 154 in the same month last year. The lowest in any month was 42 in July, against 46 in June the year before.

Weather.—The weather was remarkable for general low temperature, for the severe drought during July, August, and September, and for the heavy rainfall in May, October, and December. In the three last-named months no less a quantity than 64·26 in. of rain fell, considerably more than half the total for the whole year.

The following table shows the monthly rainfall and averages from July, 1883, to the end of 1891, and the number of days on which rain fell during the ten years 1882-91 :—

	Jan.	Feb.	March.	April.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.	Total.
1891 ... { Rainfall ...	8·54	4·20	8·50	6·22	18·53	7·14	3·76	2·70	5·87	22·85	7·46	22·88	118·65

The greatest pressure of the wind registered was 1·620 lb. per square ft. on 4th and 5th of June, this being equal to only 18 miles an hour, against 27·60 miles on 19th June last year. But, as stated in the general remarks, the wind was often strongest during the evenings and nights in June, our windiest month, after the afternoon readings were taken.

The mean daily horizontal movement of the air for the year was 97·31 miles, against 145·41 miles last year, which shews that the movement of the air was very much less this year than last. The windiest month was again June, with a mean daily horizontal movement of 239·74 miles, against 384·37 miles last year. The calmest month was January, with a mean of 31 miles, against 33·51 miles in December the year before.

The barometrie pressure and temperature of the air for the year are given in the following table :—

* Of half a year.

† Average of ten years.

‡ Average of eight years, January to June, and nine years July to December.

Barometric Pressure (5,581 ft. elevation).

1891.	Mean.	Range.
January	24.571	187
February	24.567	230
March	24.570	166
April	24.570	168
May	24.511	311
June	24.510	220
July	24.506	202
August	24.519	175
September	24.554	190
October	24.528	252
November	24.550	208
December	24.563	218
The twelve months	24.543	364
Highest reading	24.694 on Feb. 14	
Lowest reading	24.330 on May 21	

Temperature of the Air.

1891.	Mean.	Range.
January	57.5	23.5
February	59.8	21.5
March	62.2	25.7
April	63.8	23.5
May	63.3	17.5
June	61.6	15.2
July	62.1	16.5
August	62.5	20.0
September	63.3	20.0
October	62.2	15.5
November	60.9	18.0
December	60.6	16.5
The twelve months	61.6	31.5
Maximum temperature	73.0 on April 16 and May 5.	
Minimum temperature of air	41.5 on January 14.	

The highest temperature in the sun's rays during the year was 148.8 on March 22, against 149.0 on May 10 last year.

The lowest on grass was 33.8 on March 1, against 36.5 on February 18 of the year before.

The mean amount of cloud was 6.3, against 6.6 last year. The cloudiest months this year were October and December, with a mean of 8.5 each, against April of last year with a mean of 7.5. The brightest month was August, with a mean amount of cloud of 5.0, against February last year with a mean of 6.0.

4.—HENARATGODA GARDEN.

The condition of this branch remains excellent, and the various newly-introduced economic plants are progressing most satisfactorily.

Rainfall returns were kept here during the year for the first time, with the following result :—

Rainfall at Henaratgoda, 1891.

	Fall.	Days.		Fall.	Days.
January	1.93	4	July	4.82	13
February	3.32	7	August	5.43	9
March	8.29	11	September	7.01	21
April	11.19	13	October	22.51	28
May	14.44	19	November	16.91	11
June	14.30	17	December	10.58	19

Total for year, 120.17 in. on 172 days.

Comparing this with Pérádeniya, it is to be noticed that though the fall is slightly (2.46 in.) greater, it fell on much fewer (40 less) days. Even the very much heavier falls in November and June occurred in both months on less days.

This heavy rain did a good deal of damage to the paths, but most have been remade and stamped. Some old Liberian coffee has been removed to allow one path to be widened, and a good many old trees, too much crowded, have been cut out.

The Conductor's little house has been roofed with tiles in place of the old thatch.

It remains a subject for regret to me that this pretty and interesting little Garden has so few visitors. Besides a party of the boys of the Royal College (40 in number), only 34 persons came during the year. Probably the wet weather had something to do with this diminution of the number of the previous year: but it is chiefly the want of a place to stay at during the necessary waiting for the trains that makes a visit to the Garden a matter of discomfort. I have been in communication with the Government Agent as to the desirability of the establishment of a small rest-house somewhere between the Garden and the Railway station, and I believe that he has selected a site, and that a building will be erected very soon.

5.—ANURÁDHAPURA GARDEN.

The season of 1891 has been on the whole a favourable one. This part of Ceylon shared in the generally heavy rainfall, as much as 75.04 falling. On the whole it was well distributed, though there was the usual dry period from June to September, during which four months there was a rainfall of only 1.68 in., August being absolutely rainless. An unusually heavy fall of 19.42 in. occurred in May, and the last three months of the year were very wet, 36.54 in. falling, of which 11.87 were recorded in December.

As a result the trees, shrubs, and other plants in the Garden are looking very well at the end of the year, and much growth is apparent in most of them. The mastie and divi-divi trees are in fruit, and the sandalwood in flower. Teak has done remarkably well: young trees, six years old

from seed, are over 22 ft. high ; and seedling trees of *Eucalyptus alba* are making fine growth. In favourable years like this, it is interesting to find plants succeeding which are not generally adapted for the climate : thus, a cacao this year ripened eleven good pods, the seeds of which have been sown. Breadfruit and pineapples seem to ripen in most years.

In spite of these interesting results, I confess to feeling some disappointment as regards this branch garden. It has now been nine years in existence, and it must be acknowledged that its influence on the inhabitants of the North-Central Province has been very slight. In the little town itself some improvement in the gardens is observable : many now have flowers in the front, and there are beginning to appear a very few coconuts, jaks, mangoes, oranges, limes, breadfruits, plantains, and pineapples. These have been obtained from the Garden, but how small is the desire for such things is evidenced by the fact that the average annual sales have been less than Rs. 50. The purchasers, too, are almost always Tamils from Jaffna.

The Arachchi in charge is a very intelligent, industrious, and capable man, but he is discouraged by the little result of his nine years' work and the little support he receives. Our very small vote—deducting his pay, only Rs. 600 per annum—also renders it impossible to carry out even the most trifling improvements, the whole being required to pay a few coolies, whose main work is watering ; yet I scarcely feel justified in asking for a larger sum for the support of a Garden in which no one of those intended to be benefited by it appears to take the slightest interest.

We have usually had the use of a small provincial vote for "Botanic Gardens" annually placed in the hands of the Government Agent, and this has enabled me to send up cartloads of plants from Pérádeniya ; but the vote this year has not been available for us, being otherwise employed.

I hope to be able to properly roof the Conductor's bungalow, and to build brick or stone supports for the plant-house during the coming year.

6.—BADULLA GARDEN.

Our little vote just suffices to keep up routine work here, and does not allow of much progress by any additional undertakings. The principal improvement during the year has been the levelling of the main driving road, which formerly ran over a hill now cut through. The flowerbeds on either side now appear raised above the road, but this has by no means a bad effect.

The young trees and shrubs have made much progress, this being largely due to a good supply of manure regularly obtained from the town till the end of July. Some new arrangement for its disposal having been then made, we have lost this benefit for the remainder of the year ; but it is hoped that the deprivation will be only temporary. Many trees have made striking growth here, especially conifers ; a durian is 16 ft. high, and the rambutans have flowered. Brick pillars in place of wooden ones have been set up in the plant-shed, but I have not been able to finish this house or to build new cooly lines as I hoped to do.

Nor has as yet anything been done to give a better cottage to the Conductor. This is urgently needed, and I trust will be effected during the coming year.

As usual the Garden suffered somewhat from drought in the very dry weather of August and September ; but the year generally was, here as elsewhere, a wet one. In all 142.48 in. of rain fell, of which no less than 87.74 fell during the last quarter of the year, October having the extraordinary record of 41.67 in.

7.—INTERCHANGE OF PLANTS AND SEEDS.

Our mutual relations with other Botanical establishments are shown by the following lists :—

Plants.—Wardian cases and boxes of living plants were received from the following : Kew (2), Calcutta (2), Singapore (3), Buitenzorg (2), Natal (1), Trinidad (2), and from Messrs. Sander (2), Messrs. Bull (1), and Messrs. Veitch (1).

Cases and boxes in exchange were sent to the following :—Kew (3), Cambridge (1), Calcutta (2), Singapore (1), Hongkong (1), Buitenzorg (1), Brisbane (1), and to Messrs. Sander (4), Messrs. Bull (1), and Messrs. Veitch (1).

Seeds.—Packets of seeds have been received from the Botanic Gardens at Kew, Edinburgh, Dublin, St. Petersburg, Paris, Calcutta, Saharunpore, Madras, Hongkong, Singapore, Buitenzorg, Natal, Mauritius, Jamaica, Trinidad, British Guiana ; also from Baron F. von Mueller, Melbourne ; J. S. Gamble, Dehra Dun ; W. Bull, London ; J. H. Maiden, Sydney ; and L. Yates, California.

In exchange, seeds have been sent to Kew, Cambridge, St. Petersburg, Calcutta, Saharunpore, Madras, Singapore, Penang, Hongkong, Natal, Buitenzorg, Mauritius, Brisbane, Jamaica, Grenada, Trinidad, and British Guiana ; to the Agri-Horticultural Society at Calcutta, to Baron von Mueller, and to Messrs. Bull and Veitch.

My thanks are also due to the following residents in the Colony to whom the Department is indebted for plants, cuttings, or seeds, by gift or in exchange :—Lady Havelock, Mrs. Baker, Mrs.

Ballardie, Mrs. Grinlinton, Miss McLaren, and Miss Layard, and Messrs. C. H. Bagot, F. Bayley, D. F. Browne, N. G. Campbell, J. Cotton, G. de Saram, J. Ferguson, E. Hamlin, T. C. Huxley, A. J. Kellow, R. M. Knight, A. C. Lawrie, G. E. Miller, E. Mortinier, J. Regan, H. B. Roberts, J. H. Starey, F. H. Stephens, E. J. Thwaites, R. Wardrop, J. Wickwar, E. P. Willisford, and J. P. William Bros.

We have, as usual, distributed from the Gardens, free of charge, large quantities of plants and seeds to public departments, places, and persons throughout the Colony, viz.:—The Queen's House at Colombo, the Pavilion at Kandy, and Queen's Cottage at Nuwara Eliya; the Municipalities of Colombo and Kandy; the Government Agents of Batticaloa and Ratnapura; the Assistant Agents of Mátalé and Kégalla; the Director of Public Works and the Public Works Officers at Kandy, Batticaloa, Jaffna, Trincomalee, Katugastota, Mihintalé, Haldummulla, Dikoya, and Haputalé; the Principal Civil Medical Officer, Colombo, and the Hospital and Dispensaries at Kandy, Nuwara Eliya, Hanguranketa, Kahumai, and Maturata; the Assistant Conservators of Forests at Ratnapura and Kurunégala; the Postmaster, Maskeliya; the Railway Stations at Nánu-oya, Gampola, Mátalé, Veyangoda, Henaratgoda, Humpitiya, and Katukurunda; the "Happy Valley" Mission, Haputalé; the Agricultural Instructor, Nildandahinna; and the Churchyards at Nuwara Eliya and Wattegama. I have, under the head of Receipts, given a statement of the estimated value (at our ordinary rates) of these gratuitously distributed plants, &c., which ought to be taken into consideration in estimating the amount of saleable produce sent out from the Gardens.

8.—ADDITIONS TO THE COLLECTIONS.

As is seen by the following lists, my visit further East resulted in the acquisition of several interesting plants, which have been for too long *desiderata* in Ceylon. Some of these I brought back here with me, and others have been since received.

For the large additions to our collection of orchids we are again mainly indebted to Messrs. Sander, of St. Albans.

The sum at my disposal for the purchase of plants has been expended on a large collection of plants (including many roses) from Messrs. Cannell; a large collection of seeds from Messrs. Haage and Schmidt, of Erfurt; and a further selection of plants and seeds from Japan from Mr. Boehmer, of Yokohama. Most of these purchases were for Hakgala Garden. (In the following list for that Garden the large collection of temperate ferns was purchased from Messrs. Veitch in 1890, but the consignment sent in that year having nearly all died *en route*, Messrs. Veitch kindly sent a duplicate series during the past year.)

[Then follows the list of plants acquired.]

9.—NOTES ON ECONOMIC PLANTS.

Tea.—An enormous increase of more than 21¼ million lb. over last year's export—much exceeding all expectations—has been witnessed during 1891, the total export being no less than 68,274,420 lb. This greatly increased yield has doubtless been largely due to the continuous rainfall of the year. It cannot be regarded as altogether an unmixed benefit, as there seems to be no doubt that the quality has often suffered from the great difficulty experienced in properly withering the leaf. Prices ranged considerably lower than in 1890 for the greater part of the year, the average for the whole being estimated at a little less than 10*d.* per lb.

The hitherto extraordinarily rapid progress of the exports from Ceylon may now be expected to be considerably less marked; we have also now reached the point when an extension of existing markets has become essential to the industry. It is satisfactory to note that the Australian ports took 3,210,598 lb. during the year, an increase of nearly three-quarter million lb.; and that to German and Austrian ports a direct export of 237,299 lb. has taken place, showing a commencing taste for Ceylon tea on the European continent. It is noted that in England for the first time the year showed a larger consumption of Ceylon than of China tea, the figures being roughly 51 against 49 million lb.

As a whole, the condition of the plantations remains excellent. In a few places, where planting was done on shallow soil in worn-out coffee estates, the bushes have shown a tendency to die back when the roots have reached an impervious bed of rock; but considering the rapidity with which whole districts were planted up with this product, it is rather a subject for astonishment that so generally high a standard of healthy trees has resulted. I regret to notice that *Helopeltis* has been doing a little damage in some low-country estates, but nowhere has this pest assumed any serious proportions.

Coffee.—There is no change to report in the position of this cultivation in Ceylon. The export, 82,324 cwt., is much the same as in 1890, and the crop, so far as estate coffee is concerned, is mostly derived from the east of the Island.

I am however, since my visit to Java, more than ever of opinion that the cultivation of Liberian coffee in Ceylon was too hastily abandoned, and would be still a profitable one.

Cinchona.—A great drop of over 3 million lb. in our exports for 1891—to 5,679,339 lb.—shows how rapidly our trees are now being used up. Our poor barks are, however, now scarcely worth harvesting. The history of cinchona culture in Ceylon—a most interesting and instructive one—is drawing to its close; the future of the industry belongs to Java, which has followed wiser counsels and has known how to wait.

Cacao.—It is gratifying to see a substantial increase in our export of this product, the amount for 1891 (20,532 ewt.) being considerably the largest yet recorded. Prices, too, have continued very high for Ceylon cacao, which now occupies a commanding position in the home market.

Many inquiries have been addressed to me by persons interested in the West Indies as to the causes of the much higher prices reached by the Ceylon product. So far as I am able to judge, I believe it to be almost wholly due to the greater care and skill employed in the processes of manufacture, and especially to the copious washing and thorough drying of the beans. I do not think it possible to attribute it to any general superiority in the cacao here grown, for, as remarked in my last report, it holds good both as to the "Old Red" and "Forastero" varieties, though no doubt it is the fact that it is the former sort alone which exhibits the peculiar light colour of the interior so appreciated by the chocolate maker.

The distribution of seed to villagers has been continued, and about 1,000 pods have been sent from Péradeniya, and nearly the same number from Henaratgoda, to the Government Agents of Ratnapura, Kégalla, and Mátalé, for direct distribution. I followed up the remarks made on this subject in my last report by an inquiry into two applications received through the Government Agent of the Central Province, and found, as I had suspected, that the persons who were asking for seed *gratis* were not of a class who had any right to be so supplied, or indeed likely to be cultivators at all; and I of course refused to entertain the applications. In Sabaragamuwa, on the contrary, the distribution has been carried out in a proper manner, and its results are beginning to appear. At the Agri-Horticultural Show held at Kégalla in August, there were no less than eighteen exhibits of cacao.

India-Rubber Trees.—Para Rubber. I was able to supply the Forest Department with 20,000 seeds and 2,000 stumps for the plantations near Nambapána, in Sabaragamuwa, alluded to in my last report; and it is hoped there will be at least as large a quantity of seed to spare in 1892. A case of 40 stumps was also sent to British North Borneo, and 500 seeds to the German East African Company. Our largest tree, now sixteen years old, girths 6 ft. 1 in. at a yard from the ground.

Panama Rubber (*Castilloa elastica*). The Conductor of Henaratgoda Gardens prepared a sample of rubber from this for the Colombo Exhibition. It was obtained by making small V-shaped incisions in the bark (after carefully washing it) and allowing the milk to trickle down on the tree and into cocoanut shells and to dry *in situ*, afterwards pulling it off and finally finishing the drying by exposure to the sun. The sample appears to be of first-rate quality, very clean and solid, and is very dark, almost black in colour. Our best tree of this is only 3 ft. 7 in. in circumference.

Gambier (Uncaria Gambier).—The five plants at Henaratgoda are very healthy and have grown rapidly. Two flowered freely in April, and produced a few seed-pods. There will apparently be no difficulty in propagating this plant in the Colony.

I took the opportunity whilst at Singapore of witnessing the manufacture of this curious product, and though it has more than once been partially described,* I think the precise mode of procedure as I saw it is worth recording. Accompanied by Mr. Ridley, the Director of the Botanic Gardens, I visited on 11th March a Chinese plantation at Chng-chn-kong, a few miles out of Singapore, where the cultivation and manufacture is carried on. The whole industry is in the hands of the Chinese, who grow the plant—it can scarcely be said to be cultivated—on the exposed slopes amid a tangled mass of weeds, lantana, and alang-grass; the last is occasionally cut away, but no other help is given. The bushes on this plantation were five years old, and the plant lives from thirteen to fifteen years, flowering all the year round. The manufacture is carried on only when the pepper, a more valuable product, is not ready for picking. Only one sort is grown in Singapore, and whether the *U. acida*, said to afford Gambier in Penang, is really different, is very doubtful. *U. Gambier* does not seem to be known in a wild state, but Mr. Ridley tells me that the wild *U. ovalifolia* is very close, and may possibly be the same.

The Gambier plant forms a straggling semi-scandent shrub with long arching branches, and the crop consists of the short leafy twigs which branch off from them laterally. These are rapidly stripped off by hand and carried in baskets to a low thatched shed. Here are fixed large circular iron vats filled with water, which is kept in complete ebullition by large fires beneath; a constant supply of brushwood or other fuel is thus necessary for this industry. The leaves and twigs are immersed in the boiling water, and constantly stirred about and bruised for six hours by two men armed with long-handled five-pronged forks made of the very hard "Tampines" wood (*Sloetia*

* There is a good account in Begbie's "Malayan Peninsula, 1831."

Sideroxyylon). This is very tiring work. The faecid masses are then taken out and placed on a sloping wooden trough and allowed to drain into the vat so as to obtain all the extract possible.

The boiling ley is next poured into shallow wooden tubs to cool. It is now of a yellowish olive-green colour, with the consistence and appearance of thin pea-soup. When quite cool it still remains fluid, and the process of solidification is effected in the following curious manner. The operator thrusts into each of two of the wooden buckets placed before him a short, thick, smooth cylinder made of the very soft wood of "Mahang" (*Macaranga hypoleuca*), and then proceeds to agitate the mass by rubbing his fingers up and down on the surface of the cylinders. During this process the fluid gradually becomes thicker, and some solid matter coagulates on the fingers, but is wiped off. The process is continued for about a quarter of an hour, when the whole mass rather suddenly becomes somewhat contracted and of a paler colour. A few minutes after the whole "sets" into a mass of the consistence of soapy cheese, the effect probably of the crystallisation of the catechic acid of which it chiefly consists. The whole art of the manufacture is said to lie in knowing precisely when to cease the agitation: if not done sufficiently, or if carried on too long, it is said that solidification will not occur. Nothing whatever was added to the fluid at any time so far as I could observe. After a few hours the mass can be turned out as from a mould, and is cut into small cubes and finally dried in the shade; but these final processes I did not see.

Cubeb.—As one result of my expedition to Buitenzorg, I have at last succeeded in obtaining the true *Piper Cubeba*, which for so many years I have been vainly trying to get. Thirty-one rooted cuttings were obtained from the Java Garden, and 20 reached Ceylon in apparently good health. Most of these have however since died, and at the end of the year only 8 were living. I have, however, little doubt that these will succeed at Henaratgoda, if not at Péradeniya.

At Buitenzorg I found the plant grown on white cotton trees (*Eriodendron*) closely planted; they were fruiting freely. The difference in the form of the upper and lower leaves on the same plant was striking; they would never be supposed to belong to the same species. I am not however, sure that there are not two plants cultivated together as *P. Cubeba* at Buitenzorg.*

I had no opportunity of seeing the cultivation of this product on a commercial scale, and it does not seem to be carried on in W. Java. The plant, however, is apparently a wild one there, to judge from the labels of plants I examined in the Buitenzorg herbarium. All the specimens of the true plant have the leaves (however much differing in form according to age) thick, with an unequal base, alike on both surfaces, and drying of a pale colour with a pinkish tinge; the younger ones are more veiny beneath. I may refer to my reports for 1887, 1888, and 1889 for further remarks on this pepper.

Cola-nut.—A small plantation of 36 seedlings, raised from Jamaica seed, was made at Péradeniya in April; a smaller one was also made at Henaratgoda. We have not as yet found this tree to do well with us, and it is equally unsatisfactory in Java. Our trees at Henaratgoda, eight years old, have as yet made no attempt to flower.

Calumba Root (Jateorhiza Calumba).—This valuable tonic medicine is known as "Columbo" in the trade, and was formerly supposed to be obtained from Ceylon. Its name is, however, derived from the word "Kalumb," which is its appellation in E. Trop. Africa, of which country it is a native, and whence all supplies are obtained. I have been for some time desirous to add this to our rich collection of medicinal plants, but have never been able to obtain it from any of the Gardens with which we have relations, though it is reported to be growing in more than one of them. So long back as 1866 or 1867 we received a plant from Mauritius, and I find a record here to the effect that it lived for a few years only. With much surprise, therefore, this year I have discovered a plant of it in Péradeniya. The great tuberos root is sending up a vigorous stem, and unless this be the plant above referred to, which has lain dormant for so many years, I am at a loss to know how it came here.

Erythroxylon Coca.—The plant cultivated at Buitenzorg (originally obtained in 1876 from Linden, the Nurseryman of Ghent) has been distinguished by Dr. Burek from that usually cultivated (which he names *E. bolivianum*) as var. *Spruceanum*. He states that it affords four times as much alkaloid as the common kind; but there seems to be some doubt as to this. I examined the Buitenzorg plant, and find it identical with plants familiar to me in Péradeniya, where I have been accustomed to call it the "small-leaved form." We may have probably obtained it from Buitenzorg in one of our frequent exchanges. The flowers are quite white (not yellow), and the leaves very like those of var. *granatense* of Morris, but not so pale and less rounded at the ends.

* I saw nothing at Buitenzorg quite corresponding with the plant we received as Cubeb from Soerabaya in 1889 (see my report for that year) though some specimens approached it nearly. I suspect that this will prove to be *Piper (Cubeba) sumatranum* (figured in Miquel's Comm. Phyt. t. 5), which is perhaps really a variety of *P. Cubeba*. But till it flowers and fruits this must remain doubtful.

Chinese Ginger.—In my last report I ventured to express a doubt as to the correctness of the roots sent from Kew under this name, which proved to be *Alpinia Galanga*; and my remarks have received confirmation from the observations of Mr. Ford of the Hongkong Botanic Gardens. In his report for 1890 he states that he saw cultivated extensively in the rich alluvial delta south of Canton (whence the “preserved ginger” of commerce is chiefly derived) the ordinary true ginger (*Zingiber officinale*), and believes this to be after all the source of the product. He points out that the confusion may have arisen from both the plants coming under the same general name of “Keung” in Chinese.*

Fruit Trees at Hakgala.—Mr. Nock reports:—

A good many of the European fruit trees started into growth in May, but none have made satisfactory progress. The Morella cherries flowered well and produced some fruit. The raspberries, too, bore some fruit, but they tiller out so much in their growth that I am afraid they can never be profitably cultivated here. Some very fine fruit was produced on the blackberry plants, raised from English seeds—one panicle bearing 72 berries. The American sorts have made remarkably good growth, and are now sparsely showing flower buds. I have hopes that they will fruit next year. Three varieties of plums received from Japan in February have grown very well indeed, and at the end of the year showed numbers of fruit buds. I have every reason to believe that these varieties will suit this locality.

Ullucus.—On this vegetable Mr. Nock further remarks:—

The crop of *Ullucus* which was taken up in February weighed 16 pounds. This was the produce of a bed 46 ft. long and 4 ft. wide. Another small patch was taken up in March, which gave 21 lb. more. These were the produce of 2½ lb. weight of tubers planted. The 25 largest weighed 2 lb. We have had very few applicants for tubers of this plant, and unless some one should take up its cultivation for feeding pigs and require a stock of it, I see no reason to continue its propagation here. The natives, though they like the tubers very much, have not taken to growing it, and its flavour is scarcely such as to lead to its cultivation by Europeans as a table vegetable.

Palmyra Fibre.—The sheathing leaf-stalks of the palmyra, as of many other palms, contains a stiff thick fibre, and a new industry in the collection of this has sprung up, under the auspices of a Colombo firm, in the north of the Island. These fibres or bristles are much like the “Piassaba,” so largely exported from Brazil (the produce of the palms *Attalea funifera* and *Leopoldinia Piassaba*) for brush-making, and are doubtless exported hence for the same purpose. Immense numbers of the palmyra exist in the Jaffna peninsula and the islands near, and it is in the latter especially that the business of collecting the leaf-stalks for sale has been carried on by the inhabitants. In Elavaitivu the value thus collected in six months was about Rs. 3,000, a great addition to the means of the people. Unfortunately, in their eagerness for this easy method of money-getting, they have treated the trees so badly that it is reported that in that island alone 1,000 young palmyras have been destroyed. As this palm is the principal permanent source of food in the country, and is besides of immense utility for timber, fences, &c., it became obviously necessary to put a stop to this reckless destruction, and I understand that steps have been taken to regulate the fibre industry, which, properly conducted, should become a valuable addition to the means of living for the inhabitants.

Mahogany Trees.—In my report for 1888 (page 7) I recorded the receipt from the Calcutta Botanic Gardens of the seed of *Swietenia macrophylla*, a new kind of mahogany. Young trees from this seed are now very flourishing at Péradeniya, Anurádhapura, and Henaratgoda, those at Péradeniya being about 13 ft. high. This shows a much more rapid growth than the old kind, *S. Mahogani*; experience in Java is the same, and I saw at Buitenzorg trees sown in December, 1888, which were 12 ft. high.

I obtained more seed of this promising tree from Calcutta this year, and have sent 160 of the resulting seedlings to the Forest Department to form a small plantation in the North-Western Province.

The Calcutta Gardens originally received the seed in 1872 as mahogany seed, said to be from Honduras, through the India Office; and Dr. King, on its flowering, named and described it in Hooker’s “*Icones Plant.*” for November, 1886 (t. 500). Its great advantage over ordinary mahogany is that it seeds freely in the East, whilst the latter very rarely does so.

I had occasion to fell a large tree of ordinary mahogany in Péradeniya during the year, and found it very sound and free from all defects. The trunk measured, at 6 ft. from ground, 9 ft. 1 in. in girth; another tree growing in the Garden is 11 ft. 2 in. in circumference at the same level; both these trees are, I believe, just fifty years old from seed.†

* Since writing the above I have received the Kew “Bulletin” for January, 1892, in which it is now acknowledged that “in some way a mistake was made in the selection of the plant” in China, and that “it is probable that none of the preserved ginger is derived from” *Alpinia Galanga*.

† These measurements may be compared with those of trees at Jaffna given at p. 8 of the Report for 1890 of the Conservator of Forests.

10.—HERBARIUM AND LIBRARY.

Ceylon Herbarium.—All the additions up to the end of 1890 have been mounted and intercalated in their places. Four new cabinets were set up, and the whole of the additional duplicate specimens, accumulated during the last few years, have been named and sorted away into their places. The Ceylon duplicates are now all properly named and arranged, and occupy 14 cabinets.

Owing to Mr. Clark's absence on leave, my own visit to Java, and the prolonged wet weather, I have made no extended tour in Ceylon for collecting during 1891. The Garden collectors have, however, been out as usual.

The herbarium of Ceylon plants formed by the late W. Ferguson, F.L.S., which he bequeathed to the Ceylon Medical College, was during the year transferred to my Department. I have been carefully through the whole, and regret to have to say that owing to the ravages of damp and insects nearly the whole of the specimens were perfectly useless and had to be destroyed. This is less to be regretted, as Mr. Ferguson had been careful to supply the Garden herbarium with duplicates of all plants of interest which he collected.

The whole of the specimens and drawings of Ceylon *Anonaceæ* have been lent to Dr. G. King, F.R.S., of Calcutta, to assist him in preparing his monograph on this Family for the "Annals" of the Calcutta Gardens.

Dr. G. Radde, the well-known traveller in the Caucasus and Director of the Tiflis Museum, accompanied the Czarevitch of Russia to Ceylon, and made a botanical expedition in the Hambantota District. He formed there a considerable collection of plants, which I had the pleasure of naming for him.

General Herbarium.—A very large collection of plants sent in exchange (I believe in 1878) from the Imperial Museum at St. Petersburg, which had remained ever since tied up in bundles, has been taken in hand, and all have been sorted away into the General Herbarium. It proved a valuable addition, consisting of numerous specimens from the following collectors:—Skofitz, Armenia and Persia; Karelin, Turcomania; Radde, Baikal; Schrenk, Sougaria; Maximowicz, Japan; Riedel and Langsdorff, Brazil; and F. von Mueller, Australia.

From Dr. King, F.R.S., we have received from the Herbarium of the Calcutta Gardens about 300 named and mounted specimens illustrating his memoirs on *Myristica*, the flora of the Malay Peninsula, &c.

The draughtsman made 31 finished drawings of Ceylon plants and 29 of garden plants during the year.

Library.—The Garden Library has received the following books and pamphlets during the year either by gift or by purchase, and my thanks are due to the various donors:—

- Pfeiffer, Nomenclator Botanicus, 2 vols. (in 4). 1873-4.
 De Candolle, A. P., Mémoire sur Anonacées. 1832.
 De Candolle, A., Monographiæ Phanerogamarum, vol. VII. 1891.
 Hegelmaier, Die Lemnaceen. 1868.
 La Billardiere, Nouveau Genre de Palmier. 1809.
 Palisot de Beauvois, Essai d'une Nouv. Agrostographie, 2 vols. 1812.
 Seemann, Revision of Hederaceæ. 1868.
 Teijsmann, Lodoicea Seychellarum. 1868.
 Veitch, Manual of Orchidaceous Plants, Pt. 7. 1891.
 Hooker, J. D., Flora of Brit. India, Pt. 17. 1890. (*Presented by India Office.*)
 King, Two new Ilex from E. Himalaya 1886. (*Presented by Author.*)
 Id., Three new Himalayan Primula. 1886. (*Presented by Author.*)
 Blume, Flora Javae. Orchidææ. 1858.
 Boerlage, Handleiding d. Flora v. Nederlansh Indie, vol. I. 1890 (*Presented by Dr. Treub.*)
 King, Materials for Flora of Malay Peninsula, pts. 1-3. 1889-91. (*Presented by Author.*)
 Vander Sande-Lacoste, Synopsis Hepatic. Javan. 1856.
 Elliot, Farinaceous Grains of S. India. 1862.
 Greshoff, Onderzoek n. d. Plantenstoffen v. Ned. Indie, pt. 1. 1890. (*Presented by Author.*)
 Watt, Dictionary of Economic Products of India, vols. IV. & V. 1890. 1891. (*Presented by Government of India.*)
 Ferguson, The Palmyrah Palm. (*Reprint.*) 1888.
 Annales du Jard. Bot. de Buitenzorg, vol. IX., pt. 2; vol. X, pt. 1. 1891. (*Presented by Dr. Treub.*)
 Hooker's Icones Plantarum, vol. X., pts. 3 & 4., vol. XI., pts. 1-3. 1891. (*Presented by Bentham Trustees.*)
 Bailey, Catalogue of Plants in Botanic Gardens, Brisbane. 1885. (*Presented by Author.*)
 The Missouri Botanic Gardens, Report for 1890. (*Presented.*)
 Woodrow, Gardening for India. 1889.
 Commelinus, Plantæ Rariores Exoticæ. 1706.
 Murray, Avifauna of Ceylon. 1891. (*Presented by Ceylon Government.*)

As in previous years, we have added the annual volume of the following periodical publications to our series of each :—

Botanical Magazine.	Journal of Botany. (<i>Presented.</i>)
Gardeners' Chronicle. (<i>Presented.</i>)	Kew Bulletin. (<i>Presented.</i>)
Chemist and Druggist. (<i>Presented.</i>)	Nature.
Illustration Horticole. (<i>Presented.</i>)	Pharmaceutical Journal. (<i>Presented.</i>)
Indian Forester.	Tropical Agriculturist.

Acknowledgment has also to be made of the receipt of numerous Reports, Bulletins, &c., from various Colonial and Indian Botanic Gardens and other public departments.

11.—MUSEUM AND LABORATORY.

Museum.—The purchase of three more wall-cases, six table cases, and twenty-five dozen more stoppered glass jars has enabled me to exhibit a fair collection of the vegetable products of the Colony in one of the rooms. Many valuable specimens have been obtained from the fine series sent from the Northern Province and the Province of Uva to the exhibition held at Colombo in December. When completely arranged the four rooms of the Museum will be thus occupied : rooms 1 and 2, native timbers and wood specimens; room 3, native foods, drugs, and other raw and manufactured products; room 4, foreign products and botanical specimens too bulky to go into the Herbarium.

Laboratory.—Mr. J. B. Farmer, M.A., Fellow of Magdalen College, Oxford, spent nearly six months here, during most of which period he was engaged on researches on the Ceylon *Hepatica*. He left on July 8. No student has availed himself of the Laboratory for the present season.

12.—RECEIPTS FROM SALES.

The sales at Pérádeniya were somewhat higher than usual, but the total amount remains pretty steady year by year. As many as sixteen Wardian cases and twenty-nine boxes of orchids were sold to the public during 1891, mostly for export :—

			Sales.		Number of
			Rs.	c.	Purchasers.
Pérádeniya	2,210	6	368
Hakgala	593	61	100
Henaratgođa	163	72	31
Anurádhapura	71	92	46
Badulla	50	60	25
Total	3,089	91	570

In estimating the actual distribution of seeds and plants from the Gardens, there should be added to this the value of those supplied *gratis* to the Government officers, &c., enumerated on page 8. These have been for the year 1891 :—

	Rs.	c.
From Pérádeniya (about 2,000 plants, and very large quantities of seeds) value	700	76
From Hakgala (over 8,000 plants, 500 cuttings, and 16 packets of seeds) value	1,030	0

Total ... 1,730 76

In all Rs. 4,810·67.

13.—EXPENDITURE.

The whole actual cost of this Department for 1891 has been as follows :—

	Rs.	c.	Rs.	c.	Rs.	c.
Salaries and Personal Allowances	—	—	20,188	58		
Gardeners' and Labourers' wages :—						
Pérádeniya	...	8,330	0			
Hakgala	...	3,499	98			
Henaratgođa	...	2,199	99			
Anurádhapura	...	1,200	0			
Badulla	...	1,500	0			
			16,729	97		
Stationery	...				98	37
Postage and telegrams...	...				100	0
Pots, tools, books, freight, &c.	...	3,499	6			
Purchases of plants and seeds	...	443	63			
Museum	...	497	65			
Upkeep of racecourse ground	...	119	76			
Travelling and collecting	...	1,848	41			
					6,606	88
Total	..				43,525	43

Pérádeniya, February 23, 1892.

HENRY TRIMEN, F.R.S.,
Director.

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE, COLOMBO.

Added as Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for May:—

Vol. III.]

MAY, 1892.

[No. 11.

IMPROVEMENT OF SEED.

HE SELECTION and production of good seed is a subject of the utmost importance to the agriculturist, and yet no attention whatever is paid to it by the grain cultivators of India and Ceylon. Mr. Hallet, whose name is associated with the improvement of wheat in England, started his experiments some 35 years ago, and proceeded in this wise: He chose a single head of fine quality, irrespective of size or vigour, $4\frac{3}{4}$ in. long, containing 47 seeds. These grains were carefully planted in rows, one seed 12 inches each way. At harvest the plants were compared, and the best head of the best plant planted next year, and so on year after year, choosing the head from the most prolific plant. The first year the best plant bore 10 heads, the second 22 heads, the third 39, the fourth 52, the best head of which was $8\frac{3}{4}$ in. long and contained 123 grains. This was the origin of Hallet's famous "Pedigree" wheat. Mr. Hallet, writing on this subject, gives it as the result of his mature experience, that every fully-developed plant, of any cereal, has one ear superior in productive power to any others on the plant; that every such plant has one grain more productive than any other, and this best grain grows on the best ear, and the superior vigour of this grain is transmissible to its progeny: that by selection this superiority increases: that the improvement is at first very rapid, but in successive years it gradually grows less: that an improved type is the result, and by careful selections the improvement can be kept up.

Experiments conducted by Dr. Gustave Marek at the Experimental Station, Leipsic, and at Halle, in Germany, go to show that a larger, better and more uniform growth is obtained from large seeds,—the superiority being shown in every particular, in height, luxuriance of growth, uniformity, aggregate weight, number of ears or pods, number of seed, weight of seed, quality of the crop; in fact every desirable characteristic was in favour of larger seeds. Prof. Leemann of Munich had the same results. Prof. Buckman of England experimented with seeds from malformed and misshapen root crops, and finding that they produced greater deformities than their parents presented, concluded that a degenerate progeny and a poorer crop will, as a rule, result from badly-grown roots. Prof. Darwin states that since the cultivation of beet for sugar, in France, the plant has almost exactly doubled its yield of sugar, and this has been effected by the careful and systematic selection of roots for seeds. At one of the late Agricultural Conferences in Brisbane, the following piece of advice was given by Mr. David Clarke:—"Every farmer and gardener should select a well-enriched piece of ground for his seed-plot. This plot should be enriched by fertilizers to keep it up to the highest possible standard of excellence. Every tiller of the soil should acquire a habit of close observation. In passing through his crops his eye should be ever on the alert for a superior cob of maize, a cob ripening earlier, an ear of wheat with a larger grain, or possessing some superior properties. He may have several varieties to select from; let him select the best, the variety showing most good points, mark the plants by tying a piece of tape or something noticeable, when ripe, lay carefully past, and at sowing time plant it, leaving plenty of space for the plant to be fully developed. Let this selection be continued with care, and I will give a guarantee that the seed-plot will

be the most profitable portion of the farm. But remember it must be kept up to a high state of fertility."

Here then is instruction that can be followed with little difficulty, for the improvement of seed only by selection presents none of the difficulties encountered in attempting to improve seed by hybridising. Improvement by selection is carried on by tea and cocoa planters, and to some extent also by the more enlightened coconut planters of the present day, but owing to the fact of the coconut palm being a perennial growth, it will be a long time before good results are generally evident, while the bad results due to the carelessness of the coconut planters of past days, evidenced by the wretched condition of many estates at the present time, will remain yet a while to point a moral. It has been objected to in the system of paddy cultivation by means of transplanting seedlings raised in a nursery, that the plan is tedious and almost impracticable in the case of extensive paddy lands. If Mr. Clarke's advice be adopted, the result of raising up a hardy and prolific paddy crop might be arrived at by an easier though perhaps slower route: for if our cultivators keep small nurseries for improving seed, select the best seeds of the best ears each season for their specially cared-for nurseries, and sow the rest in the fields, while they improve the fertility of their land by more thorough and intelligent cultivation, they will at the same time improve the seed which is to be sown upon the land.

OCCASIONAL NOTES.

We accord a hearty welcome to Mr. Lye, M.R.C.V.S., the newly-appointed Veterinary Surgeon to the Ceylon Government. Mr. Lye will have his office at the School of Agriculture.

Mr. A. W. Jayawardene, who has performed the duties of practical instructor at the School of Agriculture since the foundation of the institution, intends before long to sever his connection with the School, whose interests he has faithfully served. Mr. Jayawardene began his studies in Science at the Ceylon Medical College, and subsequently left for Madras, where he entered the Agricultural College at Saidapet. On his return to Ceylon Mr. Jayawardene was chosen by Mr. H. W. Green, the founder of the Colombo School of Agriculture, to be the first pioneer Agricultural teacher in the Island, and be it said to his credit, that with characteristic pluck he carried on his work in an unassuming manner through little good and much evil report, and helped greatly to bring the institution into its present satisfactory condition. Owing to the death of his father, Mr. Jayawardene wishes to be free to manage the family estates, consisting principally of land granted by the Government to his late grandfather for meritorious service rendered during the Cotta rebellion.

We have received from Mr. Tiathonis, the Agricultural Instructor at Madampe, Sabaragamuwa district, a small but excellent collection of fibre and ropes prepared by him, and consisting of the following:—Rope made from Kota-dimbula patta (*Ficus hispida*). Rope

made from Kalawel patta (*Derris scandens*). Rope made from Wal-beli patta (*Paritium tiliaceum*). Rope made from Nava fibre (*Lasiociphon eriocephalus*). Rope made from Walla patta (*Gyrinops walla*). Rope made from Patharaja patta. Rope made from Patt Eppala (*Urena lobata*). Rope made from Liniya fibre (*Helicteres Isora*). Samples of nava fibre. Samples of bandakai fibre (*Hibiscus esculentus*), and rope made from bandakai fibre grown in the Experimental Garden at Wellandura. Rope made from telambo fibre (*Stereulia foetida*).

When chemical science came at first to be allied with agriculture, it was fancied that the chemist had only to analyse the soil to say what was necessary to grow a particular crop, and that if he analysed the crop after being grown he would know at once what to apply to give a full return. Chemistry has done a great deal for agriculture; but in the matter of soil analysis it has as yet been able to give farmers very little assistance in regard to what manures should be used on particular fields. The analysis of a manured crop is also little guide as to what the manure to be applied should consist of. For instance, few crops contain more nitrogenous material than one of beans, peas, or clover; and yet on land in average condition nitrogenous manures applied to these crops are not only, comparatively speaking, useless, but if applied in large quantity are actually deleterious.

The cultivation of the sunflower has spread enormously of late in Russia, and in the south-east the sunflower furnishes a prominent product of the farm. Two kinds of sunflower are grown—one with small seeds, used for the production of oil, the other with large seeds, consumed by the people in enormous quantities as dainties. The oil, owing to its nutritive qualities, purity and agreeable flavour is said to have superseded all other oils in many parts of the country, and when properly prepared is equal to French table oil in colour, flavour, and taste. Poppy and hemp seed oil have entirely given place to sunflower oil which is in great favour with the people. The cake is used for cattle food, and is largely exported, principally to Germany and England. The Government of Saratov alone exports 2,000,000 lbs. to different countries where more oil is expressed before the cake is used as cattle food, for which purpose it is looked upon as the best in Russia, being considered even better than hemp or rape seed cakes. The sunflower shells, which are used for heating purposes, not only in private houses but large factories as well, form an article of trade in several districts. The seed cups are not wasted but are used as food for sheep; if dried and ground they can be very successfully used for cattle food. The sunflower stalks gathered from the field and dried in piles, have entirely replaced firewood in South Russia; in fact, they are preferred even to pinewood, producing a great and hot fire. About 2,000 lbs. of such firewood are gathered from one acre. The total number of oil mills in Russia was, according to the last accounts, 104; of these 85 are applied solely to obtaining sunflower oil. Twenty-four mills are worked by steam, the rest by hand power. In

the Journal of the Society of Arts for March 12th, an account of the process of the extraction of the oil is given. The cultivation of the sunflower in Russia is generally considered very profitable, and it is extending owing to the increased demand at home and abroad for the seed. At the average yield of 1,350 lbs. of seed to the acre, and at the average price of $\frac{3}{4}$ d. per lb., there is an income of about £4 an acre, and this can be increased where the grower expresses his own oil. Two kinds of oil are obtained from the sunflower: the better kind is sweet and more expensive, the inferior having a bitter taste, and is $\frac{3}{4}$ d. cheaper. The oil not fit to be used as food is used in certain industries.

Professor Kinch of Cirencester, writing on plant food, in the *Farmer and Stock-breeder*, says, that the amount of water present in the atmosphere in the form of invisible vapour, is very varying, and may be from less than $\frac{1}{4}$ to 3 per cent. The higher the temperature, the more water vapour can be held in the air. In England the average amount of moisture in the air is about $1\frac{1}{2}$ per cent. An immense amount of water is required by plants to carry on their life processes and make up the loss by transpiration. It is estimated that to produce a bushel of wheat, about 15 tons of water are required. In England about 3,000 tons of water are annually deposited. There is about 21 tons of carbonic acid gas for each acre of the earth's surface. The fact that carbonic acid was decomposed by plants, with the fixation of carbon and the evolution of oxygen, seems to have been first shown by Sennebier about a century ago, though Priestly and Ingelhouz had been very near it previously. It was however clearly proved to be the case by experiments of De Sanssure and Boussingault.

The *Indian Agriculturist* referring to the Bombay Veterinary School, to which one of the assistant masters of the School of Agriculture proceeds next month, for a course of training, says:—"As a school of veterinary medicine it is doing useful work, as is evidenced not only by the number of young men trained within its walls, but also by the number of animals sent there for treatment. In its inception the hospital was intended as a charitable one for the assistance of those who were unable to pay the fees of high veterinary skill. But like other institutions of its kind its benefits are more appreciated by the rich and intelligent classes than by the poor and the ignorant. It is only natural that the knowledge of such a hospital should spread more quickly among the intelligent than among the ignorant; but when we find that its benefits are in danger of being monopolised by well-to-do clients it is necessary that some change should be made to deter such persons from using the hospital without adequate payment. At present the only charge is for feeding the animals, all the rest is free. The time has come therefore to charge a sufficient fee for veterinary attendance. The fee, no doubt, will be paid gladly, for horses are sent there not to save money but to obtain the highest skill available, and these fees will permit the society to extend its usefulness by providing large

accommodation for those who cannot afford to pay fees. If the horse stables are full the same cannot be said of the cattle sheds. There is accommodation for about two hundred beasts, of which not half is ordinarily occupied. The poor are ignorant and timid, and are naturally averse to sending their animals to a place where they are not allowed to interfere with them. They have no idea of the treatment which will be followed, of the time they will be deprived of their beasts, or of the cost which will be incurred. It is, moreover, a novelty, and the poor are suspicious of novelties. Many of them shrink from using the public hospitals when they are sick, and they do not see the use of sending their bullocks to hospital. These prejudices have to be overcome, and the hospital authorities have, we may assume, been working quietly but surely in popularising the institution. But it is clear that in the beginning the poor must be drawn to the place by the most liberal and considerate treatment, and by fees which must be nominal. When it has once taken hold of the public the rush to the hospital will be noticeable, and it will be time to raise the fees to something like the real cost."

A gentleman, whose duties impose on him a good deal of travelling, and who often meets with our Agricultural Instructors about the country, urges upon us the great importance of a proper system of inspection over the students of the school who have been stationed in remote parts of the island. By this system of inspections, we are told, the Agricultural Instructor will always have some one to consult in their difficulties, while the Agricultural Inspector will be able to personally (and that is the only satisfactory way) find out for himself what work is being done at each station, criticise and censure where necessary, approve and encourage where such action is warranted, and in fact give each Instructor such "tips" as in 9 cases out of 10 would never occur to his mind. Our informant spoke of these instructors in a sympathising tone: "Poor fellows," he said, "it is too bad to leave them all alone in some dark place of the earth and expect them often to solve agricultural problems that would puzzle an expert." In some cases, we were told, the Agricultural Instructors are under the sway and terror of some native provincial grandee who poses as Agricultural Director in his district, against whose dictum it would be madness to proceed. Others, again, we are informed, are being misdirected by those who it might be expected would guide them. Much more of the difficulties and dangers that attend the agriculturist abroad was poured into our ears, but our informant being a traveller, we may pardonably regard all we heard as "traveller's tales," till we can have the very best reason for believing it. Still, the fact remains that such things are possible, and while the possibility exists, the danger of the reality exists also.

In every department the system of inspection has been found not only to be good but absolutely essential for the satisfactory progress of the work of that department, and though a distinct agricultural department does not exist *per se*, it is most necessary that minor agricultural

officers should be regularly visited by an Inspector qualified to be conferred with our agricultural matters, involving points relative to soil, climate, elevation, rainfall, aspect and crops, and the hundred and one minutiae embraced in the apparently simple process—the cultivation of the land.

THE CULTIVATION OF THE COCONUT PALM.

It may now be supposed that the imaginary estate of 100 acres having been planted, and protected, as far as possible, from enemies, has begun to yield crops—having some 9,000 good specimens of the palm originally planted 23 or 24 feet apart. The Indian corn and manioc which was raised during the early stages will have been sold off the land and yielded a fair return. The fences will have now past the stage when they require earnest attention and may be stacked away in some convenient place to be utilized as firewood. It will now be necessary to build a store for the nuts, and select a fine high site, fully exposed to the sun, for a copra ground.

It is usual to pick once in three months or four times a year, the nuts which keep falling during the intervals being of course collected. Where trees are young and small in stature the nuts are easily picked with a very short pole, but when the trees are tall, a long pole with a scythe-shaped cutting implement bound to the end of it is used. Bamboo poles are generally used when procurable. In the case of an old estate, where the trees are so tall as to make picking difficult, the nuts are simply allowed to fall in the course of nature. Nuts to be made into copra are cut into two with an axe (4 men will cut from 10 to 15 thousand in a day) and thrown into position by small boys trained to the work, that is to say, the two halves are placed kernel upwards on clean white sand and exposed on the barbecue to the burning rays of the sun; on the approach of rain all the available lads are called in, and the position of the nuts reversed, that is, the husks upwards and the kernel downwards. When the sun comes out again the original position is reverted to, but at night the kernels are turned downwards again.

In very hot weather copra dries sufficiently in three or four days, some kernels falling out of their shells of their own accord. The bulk of the kernels are however scooped out of the shells by women and children, and the copra now separated from the shell is spread out for a final drying, and afterwards put into bags or stored away for some period before doing so.

Well-made copra should be perfectly white, and should crackle when crushed in the hand. When injured by rain or damp it gets brown, mouldy and discoloured, but will sell for not very much less than the good stuff, to owners of oil mills. In fact it is said that this latter description of copra yields oil more easily.

The drying of copra on hot sand is the most inexpensive process, and if sufficient care be exercised there need be no damage. I know of one instance where drying trays fixed to trolleys are used, but this apparatus is too expensive to become popular.

From about the middle of November to the close of the rainy season, no copra can be made, as the rain will interfere with the process. All nuts should therefore be stored till the good weather comes round again. It is a good plan not to sell nuts unless a large number is demanded for export. One of the evil consequences of selling nuts in small quantities in the neighbourhood is, that there is no chance of identifying stolen nuts.

A coconut estate is a great blessing to the people in the neighbourhood, who in addition to the small earnings resulting from fishing or raising vegetables, have the opportunity of adding to their income by giving 4½d. worth of work on a coconut estate.

R. AHERTON.

INDIGENOUS FOOD PRODUCTS: CULTIVATED AND WILD.

Chenopodiaceae.

70. *Basella Alba*, L. Sin. Niviti.

This is a plant with a twining stem. It is generally cultivated in the vicinity of houses and in vegetable gardens. The leaves are dark green and fleshy and of an ovate shape with entire margins. The flowers which spring from the axils of the leaves produce a large number of seeds in long clusters. These are at first of a green colour with a pinkish mark on the top, but when ripe they are jet black and soft, yielding a red-colouring matter in abundance when bruised.

The leaves and the stems which are all succulent are used as food made into curries. The clusters of young fruits are also much relished when fried in oil. The plant possesses very cooling properties, but native medical practitioners believe that it causes windy complaints. It is, however, one of the commonest vegetables and is consumed largely. There are two other varieties of *Basella* common here,—one is the *S. Ratniviti*, var. *Rubra*. This too is a perennial twining plant with succulent leaves and stems, but the stems and the harder tissues of the leaves are all of a red colour. It is not so common as the first noted variety, but it is used as a food whenever cultivated.

The third variety is only a modification of the first-mentioned two brought about by cultivation. The plant resembles one or other of the former, but does not grow to a large size.

Elaeagnaceae.

81. *Elaeagnus Latifolia*, L. Sin. Katuembilla.

This is a wild plant growing in the jungles of the warmer regions of the island. It has strong creeping stems with many branches having a large number of sharp spines. A characteristic of this plant is the ashy grey colour of the back of the leaves, and the surface of the stems.

The fruits are oval and are small in size. When young they are of a green colour, and when ripe attain to a pinkish white appearance, the fruit being succulent at this stage. The berries of the *E. latifolia* have a very pleasant acid taste, and are eagerly sought for by those who frequent the jungles.

Euphorbiaceae.

82. *Aporosa Lindleyana*, Baill. Sin. Kobell.

This is a tree growing in uncultivated places, sometimes attaining to a medium size but often seen as a low shrub. The leaves are ovate and entire, and have a shining green appearance.

The tender leaves of this plant form a good vegetable and are eaten made into curries.

The twigs are often used by native cultivators in shading small plants.

W. A. DE S.

BLACK SAND.

The black sands which occur on the sea-shore in some places, are composed of titaniferous iron and magnetite—the insoluble residue of such rocks as basalt. Among other places, the sands are found in the Bay of Naples, Taranaki and New Zealand.

Titaniferous iron ore (Ilmenite) an oxide of iron and Titanium, is black in colour, and occurs as a common accessory mineral in basalt and other allied igneous rocks. Magnetite, ferro-ferrous oxide, is also black, magnetitic, and found as an accessory mineral in a very large number of igneous rocks, in some of which (as in basalt) it is often abundant.

In 1868 the fact of the occurrence of black sand around the Northern coast and the possibility of iron being remuneratively extracted from it, were brought to the notice of Mr. O. Russel, Government Agent of the Northern Province, by the Assistant Government Agent, Mr. Massie. The former having communicated with the Hon'ble the Colonial Secretary on the subject, a sample was sent to the Chamber of Commerce in order to ascertain its value. In the course of this enquiry as to the commercial value of black sand, the Master Attendant furnished some information from a Mr. Holliday of Calcutta. Mr. Holliday forwarded an analysis made by Mr. Waldie, (of the Chemical works at Calcutta) who stated that the black sand contained 29.2 of magnetic oxide of iron consisting of 22.2 % of the metal and 7 of oxygen. No other metal was found to be present, and the sand was said to resemble that of Canada and New Zealand, where it was of value, and where restrictions were placed on mining and digging for it. In Canada, where the black sand was found very pure and not mixed up with silica and earthy matter, gold was associated with it, and it was stated that the occurrence of black sand indicated the presence of other metals.

The late Dr. Koch, on being consulted, declared that no graphite was present in the black sand, and that beside containing oxide of iron, it also contained black mercurial dust derived from gneiss or granite. He had not tested quantitatively for iron, but gave it as his opinion that he did not think there was sufficient iron present to pay cost of extraction.

The question also arose as to where the black sand which was so general, occurring as it did both in the North and South coasts of the island, came from; whether it was thrown up from the sea bottom or washed out by rivers from the land. Dr. Koch declared that it was brought

to the coast by the sea, being found generally in the vicinity of rocks, and was not, as supposed by some, carried into the sea by rivers from inland deposits.

NORTHERN PROVINCE JOTTINGS.

Among the fibre-producing trees of the northern province are: Thalai (*Pandanus fascicularis*), Atti (*Ficus glomerata*), Ineln (*Phoenix zeylanica*), Al (*Ficus Bengalensis*), Itti (*ficus retusa*), Maravili (*Cordia monica*), Maral (*Sansiviera zeylanica*), Erukalai (*Calotropis gigantea*), Vellam parri (*Hilicetes Isora*), Vinnanka (*Pterocarpus suberifolium*).

Other fibre-producing plants are Vel-itti, Urali, Vedatal, Tekil, Velai, Annamanna, Kayaddi, Marailupai.

Pul-paddy and pull-rice are the grain of *Panicum psilopodium* taken from ant nests where they have been stored after collection by the ants. Chilaunthi rice consists of the bulbs of a sedge (*Cyperus bulbosus*).

Tillai wood oil is the product of the tillai tree (*Dipterocarpus lewis*) and tillai wax is a species of lac produced by the agency of an insect. Tillai wood tar is prepared by burning dried chips of the wood of this tree: it is purchased by toddy-drawers to tar coconut and other palm trees to prevent ants creeping into the toddy pots. The Tillai tree grows in marshy ground. Tillai wood tar is a good substitute for ordinary coal tar.

Palai oil is used like coconut oil, and there is a trade in this oil yet to be developed. The poorer classes go in crowds into the jungle in July and collect the fruit of the palai (*Mimusops hexandra*) upon which they temporarily subsist. The expressed juice of the fruit keeps for 8 or 9 months. The fruit is produced in abundance and is suitable for making jams and jellies.

Margosa toddy is the sap which oozes from margosa trees. It is said to be good for rheumatism.

The honey of the large bee sells at about R6 per gallon; paddy and pepper are put into the honey to prevent fermentation. The honey of the small bee is deficient in formic acid; it does not keep well nor is it much used.

Urupiray arrack is named after a village called Urupiray. It is illicitly got from jaggery, toddy, and vevel (*Acacia leucaphlea*) bark, and is of a white and red (coloured by barks) colour. It is much in favour.

Mill coconut oil sells at about R1.25 per gallon; oil got by boiling sells at 5 to 10 per cent higher; gingelly, ilupai (Sin. *Me.*) and margosa at R3 per gallon; punnai (Sin. *Domba*) and castor-oil R1.50 per gallon; cow-ghee at R6 per gallon; buffalo ghee at R4.

Other animal oils and fats besides ghee, prepared in the North, are fish oil got from the fat of fish and used for mixing with resins for

dammar, dugong oil which resembles cod liver oil, turtle oil which is used medicinally, and bears' grease used in preparation for promoting the growth of hair.

The pure transparent vinegar known as crystal vinegar sells at R2 per gallon, while black vinegar—darkened by the addition of roasted paddy to white vinegar—sells at R1.25 per gallon.

Seed paddy, after a three days' drying, is stored in Mannar and the Vanny in large straw receptacles (*paddari*) or smaller ones (*churunai*). In Jaffna the seed paddy is stored in large or small ola bags, known as kudai and umal respectively.

THE KITUL PALM.

Uses.—The starch which is contained in the pith of the palm, is prepared into a kind of porridge called in Sinhalese *talapa*,—a very palatable dish, which I am inclined to think is as tasty as any plain English pudding. In the months of December or January the pith becomes full, and the people avail themselves of the season to cut down the trees for collecting the starch. It is worthy of note that those trees which have not been tapped for toddy generally contain a larger proportion of starch, probably owing to the retention of the elaborated sap within the tissues of the tree; while the amount of starch is appreciably smaller in trees tapped for toddy. When a kitul tree is cut down (which is always a fully developed one) the leaves are first stripped off, and the stem is split into two. At least, four persons are required to carry on this operation. The starch which is found collected in the upper part of the tree is sliced into fine pieces and washed repeatedly. It is then put into a clean mortar and pounded till the pieces are reduced into very minute particles. After this it is put into a strain with water. The filtrate enters into another vessel half full of water placed beneath, and settles down at the bottom in the shape of a fine semi-liquid flour. The water is then removed, and, after a while, the partially-liquid substance coagulates into a solid. The flour which is of a light brown colour is then put into a pan and gently heated over a fire and continually stirred while being heated. The result of this cooking is *talapa*—a dark brownish substance with a very pleasant odour. It is not desirable to partake of *talapa* as soon as it is prepared owing to a peculiar though not unpleasant taste which it then has; it is usually prepared in the evening and eaten the next morning either alone, or with jaggery, treacle or sugar, or with a mixture of coconut milk with a little salt. The addition of salt is not so much to bring about flavour, as to counteract certain bad effects and to promote speedy digestion. Native medical practitioners prescribe *talapa* as a very effective remedy for patients suffering from bilious diseases and other complaints. It is also good for drowsiness. *Talapa*, besides being cooling and refreshing, thus possesses valuable medicinal properties. It is

believed that one of the Kandyan Kings relished *talapa* to such a degree that he specially set apart a man to prepare this pudding and bring it to his palace every morning, granting him fields in consideration of his services. In this connection I may mention that the pith of the Katu Kitul (or wild kitul palm), which has also a pleasant taste, is eaten raw. I was surprised to see whilst ascending the Ambuluwawa mountain, which is about 3,507 ft. in height, during the last vacation, about a hundred of these palms grown in very close proximity to each other. The trees, which looked very flourishing, were grown at about the middle of the mountain, and closely resembled arecanut palms, both in height and circumference, except that the epidermis of the former is intersected with a thick coating of acicular and penetrating spines, which make it quite impossible to any mortal to climb up the tree. The sheaths are used as rude water receptacles by the poor peasants, and the leaves which are very inflammable make excellent torches. A kind of dark brown cotton is found sticking to the midribs of the leaves, and a white kind of cotton in the inflorescence. The Kandyan villagers collect this cotton, dry it in the sun, and keep it preserved in the house; and in cases of emergency when no fire is to be got, they take some of this cotton, place it on a stone, and strike it forcibly with another stone or a hammer, with the result that the sparks emitted by the concussion seize on the cotton and set fire to it.

The spathe of the kitul palm inflorescence is always used in the extraction of oil from the nuts of the kekuna tree (*Aleurites moluccana*), and also for the construction of Sinhalese measures, such as seers, chundoos, &c. I am also informed that the tender leaves at the crown of the palm are sliced and made into an excellent pickle and a curry by the people of the Southern Province, and that the spathe is also used in the preparation of "jaggery horns." If a needle-shaped splinter of kitulwood were to prick the human body, the result is a swelling of the part accompanied by much pain.

It is said that the kitul trees in the metropolis and suburbs are not tapped for toddy, owing to the difficulty of procuring the services of professional toddy-drawers. There is no doubt that the most important process connected with this palm is the extraction of toddy and the preparation of confections which result therefrom. The Kandyans are admittedly experts in the art of kitul toddy-drawing. In the course of conversation with men versed in the art, they have expressed their willingness to serve in Colombo on condition of receiving half the produce of the trees, or a month's stipend of R10 or R15 with a supply of food and cloth.

In my next contribution in continuation of this subject, I shall give a traditional account of the origin of kitul toddy-drawing, and a description of the various methods adopted in the extraction of toddy.

T. B. POHATH KEDELPANNALA.

[In my contribution on paddy ceremonies to the March number, the term for bags should be *pellali* and not *pellai*; the expression *goyanmadinawa* is used for threshing and not for ploughing.]

(To be continued.)

INDIAN FOREST PRODUCTS.

Indian forest trees, says a writer in the *Indian Agriculturist*, which number more than 2,000 species, differ entirely from those which are common in Europe; in Great Britain, for instance, there are only about 40 species of indigenous trees. The following which are the most conspicuous forest trees are referred to: The Deodar sometimes reaches a height of 200 feet; of all timbers its wood is the most durable, lasting for centuries.

The sandalwood of South India is a small evergreen; the heartwood is the valuable part, being used for incense and carved work.

The teak is hardly less durable than the Deodar, and its timber has taken the place of oak. Gold is among metals what teak is among woods. It is durable, light, not very hard, easily polished, and does not split or warp.

Mahogany is hardly indigenous, and is said to have been brought over by Carey the Missionary; the Indian timber is said to be as good as that of the American tree.

Both Sal (*Shorea robusta*) and sissou (*Dalbergia sissoo*) produce very durable timber; the sal is very hard, but the sissou is much used for furniture with fine polish.

Khair (*Acacia catechu*) produces a wood used for oil mills and rafters, as well as the valuable tanning material known as Catechin or Cutch. The Indian rubber tree (*Ficus elastica*), produces the caoutchouc exported from Calcutta; the export of rubber from India alone is sometimes of the annual value of £150,000.

It is the *people* of India, says the writer, who supply the forest revenue in their payments for firewood, charcoal, grazing dues, bamboos, gums, fibres, and other minor produce. To the Native of India the bamboo supplies almost everything, even food in time of scarcity. Besides the ordinary uses the different parts of the bamboo are put to, it is said, that under proper appliances the fibre seems destined to have an important influence on paper manufacture. The lac insect which is artificially propagated in Bengal and the Central Provinces, produces the substance which yields the shellac and lac-dye of commerce, so well known in sealing wax. The wild gums of forests are now beginning to be valued as they deserve. The yellow gum of the gurjun or wood balsam tree (*Dipterocarpus levis*) has been discovered to be a specific for leprosy. The naturalized paper mulberry of Japan yields the Tapa cloth of the South Sea Islands.

The excellent collection of forest products at the late Agri-Horticultural Show in Colombo was a most interesting and instructive object lesson, and the only pity is that the collection was not preserved in its integrity in the Colombo Museum or the School of Agriculture, and a catalogue with notes on the different exhibits was not drawn up. There is of course a collection of this nature being made by the Director of Botanic Gardens at Peradeniya, but the existence of such a collection would not lessen the value of, or interest in, a similar one that would be easy of access to students in the Metropolis.

GENERAL ITEMS.

Some interesting experiments were carried on on the three Government Farms at Seebpore, Bardwan and Samraon during the past year. At the last mentioned place, fields under paddy were subjected to deep-ploughing and treated with different kinds of manures. With transplanted paddy a mixture of crude saltpetre and linseed cake gave the heaviest out-turn, and with broadcast paddy cowdung produced the best results, while deep ploughing, to a depth of 4 or 5 inches, gave an increase in out-turn of 24 seers of grain, and 3 maunds 20 seers of straw per acre. The *Indian Agriculturist* considers these experiments uncertain, and remarks that the results of the same experiment vary much in different seasons.

Canon Bagot mentions that a substance called lactite, which resembles ivory, is now being manufactured from skim-milk. The water is expelled from the milk, and the solid matter is first compressed and then turned in a lathe into various shapes.

The plan of killing the orange scale insect in California would seem to be an intricate and expensive one. An air-tight tent is placed over the tree, and this is charged with gas generated in an open earthenware vessel by mixing one ounce each of sulphuric acid and dry cyanide of potassium with two ounces of water.

Very successful artesian well experiments have been concluded on a large cattle station in Queensland. Altogether 6 bores were made to an average depth of 2,000 feet, and in each case a supply of clear, pure water has been obtained.

Synocardia odorata, from which the fruit we know as Chalmoogra is obtained, is found in the Terai jungles, running along the base of the Garrow hills, and no doubt at one time, ere the destructive *Jhumer* so ruthlessly dealt with the forest, extended all along the adjoining ranges. The tree attains a height of about 20 feet ere it flowers, but occasionally it reaches 60 feet: and as the localities in which they are found are covered with dense jungle these forest giants are surrounded by their self-sown progeny in all stages of development. The rainfall in this Terai jungle averages 300 inches. The soil in which the plant is found is a sandy loam, submerged several times during the year by water impregnated with lime particles from the formation of that mineral, which abounds in the vicinity. The oil is much appreciated in China and Persia; but whether it possesses all the therapeutic properties claimed for it, we are not in a position to say, though we have no reason to infer the claims are exaggerated.

Mr. John Speir, of Glasgow, lecturing lately on the principles of manuring, began his lecture thus:—Plants, like animals, require a certain quantity and quality of food, and unless they are provided with such they dwindle and die, no matter how favourable their other surroundings may be. In the animal world we have one class of beasts called herbivorous, which feed on

plants, and another class called carnivorous, which feed on flesh, and the one can no more live on the food of the other than a fish can live on the land, or a cow in the water. So with plants, we have three great families, reckoned from a manurial point of view, to which all plants belong; and, as a rule, what is food for a crop of beans, peas, or clover, speaking roughly, is no more food for a cabbage or ryegrass than a bunch of clover is for a dog, or a pound of steak to a bull calf. In speaking of our own food, we have a proverb which says, 'That what is one man's meat is another man's poison,' and although this is only true of the human race in extreme and isolated examples, it is an ever-present fact in the case of the food of plants.

In the neighbourhood of dense forests, the air near the ground is moister and the dew heavier than in the open country. A gauge placed upon the crowns of the trees in forests, collects more rain than one outside at the same height. Well stocked forests are a perfect shelter against scorching winds. There is no doubt as to their value in protecting the soil and regulating the natural drainage, while they diminish floods and control torrents.

THE REPOPULATION OF PALESTINE. —Practical steps have at last been taken towards founding a colony of Russian and Polish Jewish exiles in Palestine. Finding that the funds at the disposal of the Chovevi Zion Association and those that are likely to come in are limited, and that it is not considered advisable to establish a colony with less than a hundred families, the committee have negotiated with the New York and Odessa societies, and arranged to purchase, through the intervention of Baron Edmond de Rothschild a tract of land, forty miles east of Lake Tiberias, which is described as extremely fertile. The cost of the land is two thousand pounds only, of which sum about two-thirds are already in hand. The general emigration will, we learn, be preceded by a pioneer mission, for which also funds will be required. It will consist of ten or twelve young men, who must leave their families and go out prepared to "rough it," to live in tents and till the land, to make paths and roads and to sink wells. When this work is done the first

set of families will be sent out; and from year to year others will follow as their resources increase.

The Consul for Sweden and Norway at Bombay writes to say that as the seed of Wagner's improved *Lathyrus sylvestris* and that of the wild variety are very much alike, the latter is sold for the former, with the result that the properties in the former do not appear. The Consul offers to put correspondents in the way of getting the best and hardiest seed at a fair price, and give any information about the plant.

The total import of palm oil into England is about 50,000 tons valued at over £1,000,000, but it is considered that this is an exceedingly small trade compared to what might be the case were the enormous resources fully utilized. Besides being used in the manufacture of soap and candles, palm oil is used in the process of preparing tin plates. Its non-drying qualities render it valuable as a preservative of the surface of the heated iron sheet from oxidation until the moment of dipping into the bath of melted tin, the sheets being rapidly transferred to that from the hot oil bath, which consists almost entirely of palm oil.

The students of the School of Agriculture visited the Royal Botanical Gardens, Peradeniya, and the Dematagoda slaughter-house, last term.

At the last meeting of the School of Agriculture Improvement Society, Mr. Nallatamby reda a paper on the Palmyra Palm.

Mr. J. T. de Silva of Moratuwa (an old boy, now engaged in work under the Forest Department) writes:—There is an enormous granitoid rock at the foot of a hill in this (Pasdum) Korale known as Pahiugala by the villagers who hold it sacred, and have built near it a temple. At one time wild beasts sought shelter under it, but it is now believed by the villagers to be the abode of a very large bird called by them "raja-krulla" or royal bird. Great numbers of bats also seek shelter in the hollows of this rock, and the excreta of these birds have been collected by the villagers for manuring their fields.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. XI.

COLOMBO, JUNE 1ST, 1892.

[No. 12]

FORAGE GRASSES AND FOREST RESERVES.

THE point discussed between Sir Arthur Gordon and Mr. John Ferguson on the recent occasion of the latter's reading his paper before the Royal Colonial Institute, as to the retention of forest

reserves in our higher ranges, is of interest in more than one respect. Substantially, perhaps, both these gentlemen were in real accord in their views, though these appeared to differ. Both desire that the crests of our mountains which still are crowned with forests should retain their pristine glory of wood, but Mr. John Ferguson believes that these might yet be utilized, and made to become a source of considerable revenue. The idea of the latter gentleman is that, while retaining the forest trees as conducing towards an equable distribution of rainfall, the undergrowth might be cleared away and superior grasses cultivated which would become extremely valuable for pasturing live stock. Now many experiments have been tried to improve the grasses growing in this country, but hitherto it can scarcely be said that anyone of these have been attended with success. Certainly in every instance under our own observation grasses introduced and sown with this object have rapidly and fatally deteriorated. Even with all the care and attention that can be and has been devoted to such small areas as garden lawns, that deterioration has soon become manifest; and it seems to be hopeless to expect to induce imported grasses to retain their valuable characteristics when exposed to the fierce heat of the tropical sun of this island. But Mr. John Ferguson's proposition seems to us to open out a vista of some chance at least of success. No one can have passed through the dense forests of our lower and most arid districts without coming across considerable areas of fine succulent grass growing beneath the shade of the giant trees. Of this all cattle eat freely. We do not know by what name this grass may be distinguished, but it seemed to us to partake more of the character of a clover than of grass

properly so-called. But at all events it is certain that it is a valuable fodder growth; and perhaps, were attention fully directed to the subject, it might be possible to become so acquainted with its full characteristics and with its needs as regards soil and shelter to enable it to be widely propagated throughout our hill forests when the undergrowth has been removed therefrom. We should welcome any suggestion that can be offered upon this subject. The question, as it seems to us, is as to whether it would be better to extend past experiments made with imported grasses, or to study more closely the nature and habitat of such as are seen to flourish in certain protected situations of the character we have described. So far as we ourselves recollect, the short rich grass we have mentioned flourishes on a very poor soil: It is more dependent, we suspect, upon moisture and shade than upon richness of soil; but such conditions would be readily obtainable in the forests which yet crown our hilltops. The only doubt upon our minds is as to whether the sloping land which prevails in these situations would permit of moisture being retained sufficient for the nutriment of this grass. But, on the other hand, if drainage is more rapid, so is the rainfall more constant and regular. It would be very desirable if the undergrowth were cleared in such forests to try the growth of a finer description of grass than they at present yield and which we suspect to have but little value as a fodder grass. The close short herbage of the forests of our lower country would fully supply such a want could it be induced to grow in our higher altitudes, and the attention of our foresters might profitably be given to some experimenting with it in the direction named. From opinions offered by the late Director Thwaites of Peradeniya and from experiments tried on the Nilgiris by the Madras Government Botanist Dr. Lawson, it seems certain that several of our indigenous hill grasses can be largely improved in fodder quality by being converted into hay. There would be the additional advantage in this process, that the utilization of forest-grown grasses in this mode would obviate the objections which forest officers might offer to cattle grazing amongst the forest trees.

PREHISTORIC CORN.

A dispatch from Burden, Kban, says:—A. J. Mercer, living near this city, has a patch of corn which is the rarest ever grown. The patch is small, but the grain is a kind that has never been seen in this country before. Last spring Mr. Mercer opened an ancient mound on his farm, and in it found a lot of corn, along with certain prehistoric relics, showing that the corn had been put in there years ago. There

was a peck of it, and it was in a sealed jar. He gave about half of it away to neighbours and others who wanted it for a curiosity. He thought it would be a good idea to plant some of it, and prepared a piece of ground near his house for that purpose, planting about two quarts of the seed. It sprouted and thrived well under cultivation given it. The ears came well, when harvested. They are about six inches long, and the grains, which are small, being about one-fourth the size of the ordinary corn, are close together, standing up with sharp points. Mercer thinks that this must be the original corn of the country, from which the present Indian corn has sprung through long and high cultivation. What is remarkable about it is that the mound from which it was taken is undoubtedly very old, for on it are growing trees that show by their rings that they are over 200 years old. The relics found with the corn are similar to those found in mounds of Ohio and Illinois, and this mound must be co-existent with those which are thought to be over 1,000 years old. Mercer has sent samples of his corn to friends in the East and the Government officials at Washington.—*American Miller.*

THE HOME OF THE TEA KING.

(Communicated.)

Crowning a respectably sized hill somewhere about five miles beyond Stanger township the traveller notices an extensive, imposing building in Renaissance style, which commands a vast and distant view, even as far as to the Etshowe camp in British Zululand. The rugged, hilly nature of this part of Natal has not interfered with what has turned out a remarkably successful colonial industry, viz., the tea planting, and it is no idle boast to say that the success of this now flourishing industry has been due to the indomitable perseverance and dogged pertinacity of our energetic colonist, Mr. John Liege Hulett, M.L.C. The start of this great work was made with a few hundred tea bushes in 1887, which were obtained from seed as far back as 1880. The preliminary five acres of five years ago have developed into over 300 acres on Kearsney estate alone, quite 170 acres on Mr. Hulett's adjoining estate, Kirkly Vale, and over 100 acres on a third and new estate called Bulwer, situated about nine miles from the first, the leaf being, however, all treated at the central works adjoining Kearsney Hall.

The Bulwer estate specially will be worked on the Central Mill system, that is, leasing portions of the land to small growers, the proprietor purchasing the leaf and manufacturing as before mentioned.

Being a great lover of good tea, the visitor soon spotted the active anti-responsible leader in one of the enormous fields, covered with the profit-bringing low bush, planted in long rows of marked regularity.

The information required was most willingly given by Mr. Hulett, who said the Natal tea plant was originally obtained from Indian seed, a variety of Assam, and proved itself admirably adapted for the colony, so much so that the yield in Natal per acre is far in advance of the same tea per acre in India, and fully equal to the producing power of other tea countries, such as Ceylon, &c.

"Mr. Hulett, it has often been stated that the rainfall in Natal is too small to give a successful tea leaf crop, compared to India and Ceylon? As one of the veteran growers you can no doubt give me information on this point?"

Mr. Hulett answered deliberately, that his experience was the hard fact, that with the smaller rainfall the returns are actually larger in Natal than other tea-growing countries, because in these the rain comes down with tropical violence in great masses, whilst in the garden Colony of South Africa the rain descends in the form of genial showers, which the thirsty land absorbs thoroughly, and the water therefore is not wasted. The rainfall in this part of Victoria County is usually about 35 to 50 inches per annum, and the usual climate experienced is the day breaking with heavy fogs, obscuring the distant country, and on lifting giving a hot sweltering heat which is most suitable for tea culture. No frosts are experienced which would be fatal to the plants.

Tea takes seven years to mature, though the first picking is done at the end of the third year from time of planting, increasing year by year as the plants develop. The yield and quality of the leaf depend entirely on the class of soil, favourable seasons, and care bestowed in cultivating the plants. Between the second and third year the yield of the tea leaf, that is, the light green flush or young leaves which sprout out on the top of the bush, may range between 100 lb. to 200 lb. of dry tea per acre, and even more. The following season that return may be doubled, and by the time the tea bush is at its maximum power, the yield can be from 800 to 1,000 lb. of dry tea per acre per annum. The proprietor of Kearsney has, for instance, taken from an area about 20 acres in extent quite 1,200 lb. of dry tea per acre in a year, and that from plants between five and six years old. This wonderful bush gets an age of quite 25 years, but in Indian plantations, plants growing for 20 or 40 years are still flourishing; and it is also interesting to learn that the tea tree grows naturally to a tree, ranging from 28 to 30 feet in height, with a stem having a diameter of about six inches, but is, of course, always kept stunted to a bush not above two or three feet in height. It is cultivated for plantation purposes in long rows, each bush four to five feet apart, and trained by pruning into the shape of saucer-shaped tops, in order to have the maximum area extent for picking surface. At Kearsney Estate the plantations cover hills and valleys for long distances, and are protected by huge hedges in the shape of tree belts, mostly blue gums, which break the cutting power of the winds.

The natural labour supply of Natal only being available to a very limited extent the veteran tea planter finds it necessary to employ about 200 Indians, who, with their wives and children are all busily employed either in the fields, picking leaf or pruning and weeding plants, or in the large works, of which a description follows. To the casual visitor in Natal it is most pertinent that the many agricultural and planting enterprises in the colony in which large capital has been sunk, similar to the tea industry that takes years to develop, the whole success depends entirely and solely on a reliable and steady labour supply, which is efficiently kept up by the Indian immigration system. In contrast to this, the genus "Arab merchant" might well be dispensed with, for more than one reason, from the colony.

The yield of tea in 1887 was about 300 lb. This industry has developed in the last five years to such an extent that this season a market will have to be found for Kearsney teas for over 300,000 lb. of dry tea.

The adjoining tea plantations are Olifon and Nonoti from which large quantities of young teas are being sent, also some very good qualities, and from 10 others; from the latter the leaf is all manufactured at the extensive Kearsney works. The total extent of the tea planted in the immediate neighbourhood of Kearsney is about 1,500 acres.

Being anxious to know how the tea is made into the palatable beverage "we all love so," from old ladies downwards, I followed the genial proprietor into the large works adjoining the stately mansion, and here met Mr. Drummond, the gentleman who is in charge of them. From him I gained the following interesting details regarding the various processes.

The green leaf is brought into these works by the coolies who deposit their baskets, containing about 25 lb. on the scales to be weighed. It is calculated that the green leaf is about four times the weight of the dry tea; that is, 1000 lb. of green leaf will yield about 250 lb. of tea. From the scales in the basement, the leaf is carried to the withering lofts, where it is evenly and thinly spread out over huge flat stacks by the active and rapid hands of dozens of little coolie children. This being the first process, takes about 12 hours on a warm day. Usually the plucked leaf is ready the next morning to undergo process No. 2. From the lofts the now withered leaf passes through

shoots below into the huge iron rollers driven by steam, and consisting of two large flat tables moving in rapid rotating motion. Usually half-an-hour suffices, but in cool weather it is often extended to an hour. The third process is the fermenting stage. This is a most important process, as under-fermentation produces poor quality tea, and overfermentation is fatal to quality and gives sour tea. The leaf is fermented to a bright even salmon colour, and when the correct stage is reached, it passes into the drying machine, called a Barry & Gibbs' long, cylindrical, rifled dryer. The tea leaf once inside is precipitated round and round for about 15 minutes in an intense heat, and after the whole tea leaf has passed through, it goes through the same treatment a second time more rapidly, and issues from the machine virtually as tea, as we know it. The remaining process is the fourth one, viz., the sifting. Various sives, with of course differently-sized meshes, produce the fine or rough qualities in the tea; the rougher kinds being the poor sorts and cheaper ones.

These large works at Kearsney are well worth a detailed visit. Ample lodging accommodation, two huge steam rollers, two patent dryers, sifters and cutting machines, with two steam engines of not less than 10 horse power, do the ever increasing work. Large store rooms, where an enormous stock of tea is kept in bins, with a large packing department, with busy chindroon packing up the fragrant leaf and labelling packets for outside trade form a busy and most interesting scene. Mr. Hulott's sturdy sons have built nearly the whole of these works, including a large steam saw mill, where the trees from the estate are cut up until they issue as neat packing cases and also extensive stabling. Over 200 Indians are employed on the estate, who are in charge of Sirdar Poniah Pillay, a learned Bengalee, who, besides supervising his deck, is quite capable of entering into a philosophical argument with the visitor.

Kearsney Estate, its proprietor and his family show a most remarkable illustration of the old proverb, "Unity is strength;" and that the industry initiated by Mr. Helett and his family will prosper to a still greater extent must be the sincere wish of everyone who desires to help in the local watchword: "Advance fair Nat'l."

MR. A. ROSS'S PAPER ON PERU.

MR. CLEMENTS MARKHAM ON CINCHONA PRICES.

At Monday's meeting of the Royal Geographical Society Mr. Alexander Ross read an interesting paper on his journeyings in Peru. Mr. Ross is a Ceylon planter, who formed one of a small party of Englishmen sent out to Central Peru last year under the auspices of the Peruvian Corporation (Limited)—to whom a considerable part of assets of the country has been pawned by its rulers—for the purpose of investigating its economic resources from a planters' point of view. In the course of his paper Mr. Ross observed that he had come across a Peruvian coffee-grower who had many cinchonas around his coffee-fields, and who told him that fifteen years ago, when he started coffee-planting, the land was covered with large numbers of the same trees; but, as he did not know what they were, he simply had them cut down and burnt. (N.B.—South American cinchona bark was worth from 3s to 5s per lb. at that time.) Mr. Clements Markham was present at the meeting, and took part in the discussion. In the course of his remarks he called attention to the fact that whatever economic products Peru produces are usually the best of their kind; and he instanced coffee, rubber (the Pará rubber of commerce, much of which is really produced in Eastern Peru), wool, and cinchona. Although of the 43,000 bales of bark imported into London in a year only 8,000 came from South America, he said, it was a significant fact that East Indian bark did not now rise in value above 9d per lb., whereas that grown in Peru realised 1s 9d to 2s per lb. The moral he deduced from those figures was that "if you (the Peruvian Corporation) undertake the cultivation of cinchona on your new land in Peru, the average prices of bark will advance to more than double o-

what they are now." It may seem presumptuous to contradict Mr. Markham on a subject upon which he is so eminent an authority; but we must take leave to challenge these statements of his. The cinchona barks to which he apparently alludes are the "Loxa" and "Huanoco" barks of commerce, which realise high prices (though not so high as he stated) not on account of their richness in quinine—which is much less than that of good East Indian bark—but simply because there is a certain demand for them in some Continental countries for certain pharmaceutical purposes—a demand which rests, we think, entirely upon a fanciful basis, and which would be altogether unequal to the absorption of large quantities than are now placed upon the market. Apart from this, the cost of carriage and of harvesting these barks is so great that they could never pay if grown as quinine barks. The cultivated Calisays of Bolivia have not paid their growers for a long time. Only last year, as we announced at the time, one of the principal among them had to give up the struggle, and about the worst use, we should think, to which the Peruvian Corporation could put their acquisitions would be to plant cinchona upon them.

THE PIONEERS OF THE EASTERN CINCHONA INDUSTRY.

Mr. Ross's statement that "the valuable medicinal plant cinchona was first introduced to the Eastern world by Mr. Clements Markham" is also one which in justice to a distinguished botanist now living in ripe old age and in close retirement in a small Gorman country town, should not pass unqualified, especially as the services rendered by Mr. Markham himself are so conspicuous that his brilliant reputation can suffer nothing by the recapitulation of the strict facts of the case. Leaving out of account the introduction in the forties of cinchona plants and seeds by Weddell into France, and by certain unnamed individuals into Algeria, as these efforts led to no practical result, the honour of first introducing the cinchona plant into the "Eastern world" belongs unquestionably to Joann Karl Hasskarl, a German hotarist sent to South America in quest of the plant by the Dutch Government, and who, after a long and perilous expedition, delivered twenty-one Wardian cases of cinchona seedlings on board of a Dutch man-of-war, sent there expressly to receive them, in the port of Callao on August 21st, 1854, some years before Mr. Markham set out from Europe. Hasskarl's surviving plant reached Java in December, 1854. Mr. Markham shipped the 456 seedlings which were the pioneers of the cinchona industry in British India at the port of Islay, in South America, in June 1860. But in the meantime a quantity of *Lanceifolia* seed, procured by Karsten in Colombia, had also been sent to Java on account of the Dutch Government in 1854. Mr. Markham's exploits might also have been run close, but for untoward accidents, by Mr. George Ledger, who, about the same time as Mr. Markham himself, succeeded in collecting a supply of seeds and plants in Southern Peru, but whose expedition was destroyed by Indians on its way to the coast. It is owing principally to Mr. Markham's powerful advocacy of the claims of his less fortunate rival that Mr. Ledger's merits in the pioneer-work of the cinchona industry have been somewhat tardily acknowledged as they deserve. Fückiger and Haubury, in the 1879 edition of the "Pharmacographia," for instance, make no mention whatever of Mr. Ledger's expeditions.—*Chemist and Druggist*, April 1st.

SALE OF CEYLON GOLDEN TIPS IN SYDNEY.—The *Queenlander* of 2nd April says:—

Messrs. Murrell Bros., of Sydney, have forwarded us a sample of the golden tip Ceylon tea, which was offered at Messrs. Fraser and Co.'s tea sale last week on account of Messrs. Parbury, Henty, and Co., and of which they became the purchasers after brisk competition. The price paid was 5s per lb. A larger price for a similar sample has been obtained in Melbourne, but this is the highest sum ever paid for tea in the Sydney market. The tea is of excellent flavour, having that delicate aroma which is a distinctive feature of the Ceylon leaf.

REPORT ON PERU BY MESSRS.
A. ROSS AND A. SINCLAIR.

We now publish (see page 885) the Report of the Commissioners, and very able and interesting it is. We feel as we read that of a large portion of the land of the Incas it may be said, "If there is an Elysium on earth it is this!" It is a land of tropic luxuriance, the forest trees of which are said to dwarf those of the Ceylon jungles into insignificance, with a soil rich beyond comparison, requiring only to be scratched, or in the dry region irrigated to laugh with abundance of all possible products, from wheat and potatoes, to coffee and cacao. With all this the demon malaria does not baunt this earthly paradise. How he came to be banished is the problem we should like to see solved; for prominent in history stands the record that the Countess of Chinchon, wife of a Viceroy of Peru, was cured of malarious fever by a decoction of that "Peruvian bark" which perpetuates her name in the mutilated form in which Linnaeus wrote it, and which Markham has chivalrously but vainly striven, although with the aid of the Indian Government, to restore to its proper proportions in the shape of CHINCHONA. Thomas Moore during a visit to Byron in Italy commenced a glowing appreciation of a glorious sunset when his brother poet stopped him with "Come, Tom, don't get poetical." The Commissioners from the Peruvian Syndicate having no mentor but their own Scotch sense of propriety and "dunceness," that state they found it difficult in describing the land and its riches to adhere to the usual sober language of official reports. On the banks of the Perené river there is the selected tract of forest land one and a quarter million acres in extent interspersed with a few "pajonals" (the equivalents of our pastures), the forest trees being magnificent, while the wealth of orchids gave evidence of sufficient rainfall for coffee and other tropical products. The nature and the luxuriance of the vegetation were the only means available to the Commissioners by which the amount of rainfall could be estimated for, Messrs. Ross and Sinclair affirm that not only has no record of the rain ever been taken in Peru, but that such a thing as a rain-gauge has never been introduced into the country! What has the representative of Peru in Britain, who recently read a paper on his country, to say to this token of backwardness? He can no doubt point in compensation to a railway which ascends the Andes to over 12,000 feet altitude, and to a series of good roads in course of formation. But in most countries an essential preliminary to such works is to ascertain the rainfall to which the works in course of construction and when completed are likely to be subjected. Peru is, however, a land of anomalies, a tropic land with a rainless seashore climate, varying only from 68 deg. to 72 deg.; no malaria, no land leeches, very few mosquitoes, and wheat and potatoes growing to altitudes of 8,000 and even 10,000 feet, while the Peruvian satinwood is an ebony. The "alfalfa" (lucerne) grows luxuriantly; and on the elevated grass lands llamas, vicuñas, alpacas and sheep in plenty are fed. Specimens of cinchona—sucubra and calisaya—were seen 6 feet in circumference! These trees had probably seen Peru a Viceroyalty of Spain. The coca plant, so valuable for the anesthetic it yields, formed the undergrowth in much of the land selected, and its cultivation on a large scale is recommended. The land is in 11 deg. South, and is described as suitable for tea amongst other products; but as the Commissioners

specially describe the land and climate as differing from those of Ceylon in being a land of flower and fruit, rather than of leaf, we should think attention will be specially directed to such products as coffee (which yields at the rate of 24 cwt. an acre) and cacao. The great difficulty will be that of a good labour supply. The indigenous labour cannot be depended on, and there are but few Chinese left of those introduced in former years. We should think, therefore, that all the labour which can be procured will be required for the cultivation of coffee, cacao and coca. It is stated that the Chinese make good labourers is kept away from centres of population, but naturally enough the chief reliance is placed on Tamils, so that we may ultimately look for competition from Peru in our region of labour supply. We need not be much alarmed, however, as the Indian Government is not easily satisfied with the proposals to remove its people to remote and foreign countries. Like Mr. Clark, Messrs. Ross and Sinclair, in their glowing accounts of Peru, say nothing of liability to seismic and political disturbance. The Commissioners make much of the exemption of Peru from the effects of tearing monsoon winds, and that evening breeze which in Australia is so disagreeable and in India so deadly. But we in Ceylon are beyond the region of volcanic disturbance, we enjoy the *par Britannica* and with occasional little difficulties we have the essential advantage of a sufficient, steady and reliable labour supply. There is one point in this able and interesting report, regarding which we should like to have an explanation. It is stated that there is a potato yet to be introduced from Peru superior to anything hitherto known. Let us have this new variety of potato by all means. It is amusing to read that besides calculating the rainfall by the general character of the vegetation, the proper zone for coffee was indicated to the ex-Ceylon planters by the existence of *ageratum*,—the much abhorred "white weed." It is also curious to learn that oats are a prevalent indigenous weed in Peru, while such exotics as the Australian eucalypts flourish amazingly. Amongst the native trees is a beautiful evergreen willow, which, it is believed, would be a great acquisition to Ceylon. The species of screw pine of which the Panama hat is made is also common. Cultivation is carried on in this wonderful country to over 12,000 feet altitude, while grazing is successful up to 15,000 feet. Only the mineral region seems to be cold, barren and so rugged as to be difficult of access. Extensive pampas and beautiful lakes are spoken of as adding to the attractions of the scenery. Sugar culture at present absorbs attention in Peru, the rum which accompanies it being unfortunately a source of demoralization of the people as well as of profit to the distillers. Let us hope that this culture may be superseded by that of coffee, which with irrigation can be grown almost anywhere in Peru, under 7,500 feet of altitude. At present rates of transport by pack animals are prohibitory, and so a railway is recommended in addition to water carriage on the Amazon, for the accommodation of the tract selected on the banks of the Perené. Naturally enough, a land in which wheat, barley and potatoes grow in close juxtaposition with sugar, coffee and other tropical products is deemed suitable for being colonized and settled by men of all races and from the most varying climes. With the opening of the Oroya railway, and the completion of roads in course of construction, it is stated, the facilities will be all that could be wished and such as never previously existed in Peru.

FROM THE METROPOLIS.

April 1st, 1892.

"PERU" AND THE ROYAL GEOGRAPHICAL SOCIETY.

The reading of the paper by Mr. Alex. Ross took place on Monday evening last, and I send you a copy of the same, for which no doubt you will be able to make room in the *Literary Register* as well as *Tropical Agriculturist*. Here it will be sufficient to give the summary which appeared next day in the *London Times*:—

CENTRAL PERU.

Last evening, at a meeting of the Royal Geographical Society in the theatre of the University of London, Burlington-gardens, a paper by Mr. Alexander Ross, on "A Recent Journey to the Head Waters of the Ecayali, Central Peru," was read by Sir Alfred Blunt. Sir M. E. Grant-Duff, the president, took the chair. There was a good attendance, including Lord Donoughmore, Mr. Clements Markham, Sir Beauchamp Walker, General J. T. Walker, Major Darwie, Colonel Church, Mr. P. L. Selator, Señor Pezet (Peruvian Consul-General), Mr. J. Scott Kettle, and the author of the paper, who is understood to have been prevented by a cold from reading it himself.

Mr. Ross said that the journeyings of which he proposed to give some account were undertaken by desire of the Peruvian Corporation of London for the exploration of the central territory of Peru, with the view of selecting and inspecting lands which the corporation had the right of acquiring, and to report generally upon their suitability, climatic conditions, and other matters affecting the industrial geography of that part of the country. He was accompanied by Mr. Arthur Sinclair, who, like himself, had spent many years planting in Ceylon; and also, for research in economic botany, by Mr. P. D. G. Clark, assistant at the Royal Botanic Gardens, Peradeniya, near Kandy, Ceylon. Their travels, which lasted five months, were confined to the central portions of the interior, and extended, leaving out the railway journey from Lima to the terminus at Chicla, from the latter point in the direction of the Amazon basin as far as the rapids the Rio Perené on the east, the towns of Cerro de Pasco and Huancayo—the latter on the Rio Huallaga—on the north, to Janja, Huancayo, Comas, and Andamarea on the south and south-east, also, to a limited extent, on the western coast north of Callao. The area visited was not of great extent, regard being had to the immense territory they had set out to explore, and had been visited by several competent travellers in the past, while in quite recent years the Peruvians themselves had done much for a knowledge of their interesting country. After a close description of the country, Mr. Ross stated the conclusions at which he had arrived. Not much of the Sierra visited by them, he said, was suited to modern systems of tillage. But in the Montana there were vast areas at suitable altitudes well adapted for settlement by European immigrants. In the lower parts of the Amazon basin, in a climate more or less suited to white labour, immense tracts awaited only the introduction of Chinese or the Indian coolies to turn what was now a magnificent forest wilderness into a rich and thriving province. The Central Railway would have been completed to Oroya in June next, and the Chanchamayo road would be opened soon thereafter. In continuation of these, and to connect them with the navigable waters of the Amazon, the survey of a railway line had already been ordered. The immense influence these would have upon the future of Peru and its progress would then become apparent. At present, to those who had not seen that country's varied and unlimited mineral resources, its grand forest, its rich soil and splendid rivers, a full realization of the future of Peru was impossible.

In the course of the discussion which followed the reading of the paper,

Mr. Clements Markham dwelt upon the improved

fertility of Peru, pointing out, among other things, that four crops of maize were to be got there every year, and that each head of this maize was four or five times larger than that of any other part of the world.*

Señor Pezet and Lord Donoughmore also bore testimony to the opportunities which the natural richness of the country afforded.

I may mention, in addition to the above, that the dinner which preceded the lecture Mr. Ross had the opportunity of giving in a few minutes a brief indication of the contents of his paper, at the request of the Chairman, Sir M. Grant-Duff, in responding to the toast of his health. The Chairman was further interested when he learned that Mr. Ross's colleague was his old acquaintance Mr. Sinclair who took Eden House, Banff, from Sir M. G. Duff, when he retired from Ceylon. At the public gathering, there was a fairly good assembly, though "Peru" is not so attractive a subject as the "Antiquities in Mashonaland" which in Mr. Theodore Bent's hands, drew an overflowing meeting, or even "Ceylon" which filled the "Whitehall" Room. Sir Alfred Dent read the paper very deliberately, while Mr. Ross pointed out the different places mentioned from time to time. After that, there was an exhibition of a number of interesting photographic slides by lime-light, showing views in the Andean railway, tunnels, gullies, &c., also bridle paths traversed, and in the Perené river and forest, tomb of the Incas, markets of the Indians and so on.—THE PERUVIAN CONSUL-GENERAL (whose lecture on Peru was recently given) opened the discussion, and he was followed by LORD DONOUGHMORE, a hardy epicure of the British, or rather Irish peer, who has large interests in Peru where he has spent 2½ years. He thought enough had not been made of the sugar enterprise, which he maintained was in as favourable not to say strong a position as any planting industry in the world and able to compete profitably even in these days of low prices and Continental adverse duties. He spoke in high terms of Peru and its people and the rainless region where irrigation did such wonders. To him succeeded Mr. CLEMENTS MARKHAM who, of course, spoke with authority and with a wider scope of knowledge than anyone else present, respecting a country of which he had made so special a study. He gave a very interesting *résumé* of the early history and referred to unpublished manuscripts in his possession, descriptive of certain districts and resources down to minute particulars, by Spanish monks and travellers. Then he gave a general picture of the outlook in the different divisions of Peru, telling us how one portion greatly resembled the Nilgiris save that in place of the colouring afforded by rhododendrous (when in flower), there were flowering shrubs of other varieties and colours but equally striking and gorgeous. Then as to products, Mr. Markham maintained that the great matter was the superiority of the quality of these in Peru, rather than the greatness of the quantity. Peruvian coffee, for instance, was absolutely the finest in the world. [I thought of Mocha, and no doubt the dry Peruvian climate is comparable with that of Arabia.] Then in cinchona India and Ceylon might send some 40,000 to 50,000 bales to Europe against 7,000 from South America, but see the vast superiority of the latter—double and more in value per lb. And so with "Rubber," how vastly superior was the article got from the Amazonian basin to that of Africa or Asia; and so with "Cocoa"; and then there was "Coca" which required the

* Mr. Clements Markham's highest character alone induces us to credit four crops per annum of maize with cobs four or five times the usual size!—Ed. T.A.

most careful handling—as much so as tea—in the leaves; and still again the Indian corn of Peru where was its equal; or the wool of the country and so on!

I felt much inclined to get up at the end of this, and correct Mr. Markham in respect of cinchona bark, by pointing out how the South American article came from trees of great age, or at any rate of maturity, while in India and Ceylon, the planters had to harvest back from comparatively young trees, not because if left alone these would not have developed a richer bark, but from necessity—in too many cases, it was with Eastern planters:

My poverty, and not my will consents.

But it was getting late and there was no time. Col. Cronin followed in a long and rather prosy speech which gradually sent away a good many and tired out the President, who jumped up at its conclusion, proposed a vote of thanks to the writer of the paper and hastily left.

One paragraph, arising out of Mr. Markham's speech is given in the *Daily Graphic* as follows:—

On the authority of Mr. Clements Markham, speaking at the Royal Geographical Society on Monday evening, Central Peru has amazing fertility, four crops of maize being obtainable from the soil in one year! Moreover, the cobs of the corn "are four to five times larger than the heads of any other part of the world." Now, as we can grow in Essex and Norfolk thirty tons of green maize to the acre—planted in May, and gathered early in October, with tasselled heads fully eight inches long—the marvel crop of Peru would produce 120 tons to the acre with cobs two feet long. Such a wondrous result would read like a "traveller's tale" but, coming from Mr. Markham, has to be accepted as authentic record. At the present date the maize crop of La Plata is on offer in London, May-July shipment, at the very low price of 19s 9d per 480 lb. underselling the cheapest American maize, 20s 6d, and unsetting the English trade, being 2s 6d a hundred weight cheaper than ours.

THE CEYLON AND ORIENTAL ESTATES CO., LD.

I enclose the prospectus, just out, of this new Company alluded to previously by me. No doubt the Ceylon Agents will give the opportunity for local investments by advertisement. The Board of Directors is a strong one with Mr. Hugh C. Smith, Director of the Bank of England, as Chairman, and Messrs. H. A. Hancock, Cyril E. Johnston, T. J. Lawrence (formerly of Ceylon), C. A. Reiss—all men of high character and standing in the City—not to mention the Managing Director, Mr. Huntley Thring, who is a tower of strength in himself. Mr. A. J. Denison continues to be Inspector of Estates, and Mr. Hugh Chpman, Secretary,—both capital appointments,—as the Ceylon and Oriental Investment Corporation, Ltd., is absorbed in this new Company. Already £100,000 of debentures have been provided for, so there can be no doubt of ample financial support, and it will be noted that out of £250,000 nominal capital, only £150,000 is to be called up. As for the rest the prospectus can only be quoted, and all good wishes offered for the success of this young set, but by no means least powerful or important of Ceylon Planting Companies:—

PROSPECTUS.

This Company has been formed primarily to take over as a going concern the Business, Estates, and Assets, of the Ceylon and Oriental Investment Corporation, Limited, a Company formed in 1890, with a capital of £37,050, subscribed by the Directors and their friends, including in such assets the Tea Estates known as Moridoya and Wilton, Pathragalla, Narthapana and Deegalla, well secured advances on estates and crops, and the benefit of a contract which the corporation recently entered into with

Messrs. Baring Bros. & Co., for the purchase from them of the following further important estates in Ceylon, viz:

Bogahawattoc.	Le Vallon.	Peacock Hill.
Peradenia.	Keenakello.	Rajatalawa.
Wiltshire and Hampshire.	Denegama (one half).	Oodewello (one half).

The opportunity of acquiring these estates being exceptional, the contract has been arranged on terms which the Directors of the corporation considered to be advantageous, but the constitution of that Company appearing inconvenient for the purpose of carrying out this contract and others in contemplation, it was decided to reconstitute the corporation by the formation of the present Company.

The Company has also entered into a contract for the purchase from Mr. J. Huntley Thring of the Ceylon Estate known as Wangie Oya. Mr. Thring, who has accepted the appointment of Managing Director of the Company, has agreed to take payment of one-half at least of the price of the above-mentioned Estate in Shares, thus retaining a substantial interest in the Company, and he also guarantees the net profit from the working of the Estate during the next three years to average not less than £2,500 per annum.

The price to be paid to the Ceylon and Oriental Investment Corporation, Limited, for its goodwill, property and assets, as above mentioned, is £37,050 in ordinary shares of the Company credited with £3 per share paid up thereon, to be issued in substitution, Share per Share, for the Ordinary Shares issued by the Corporation, and £1,176 in cash, and 392 fully paid-up Preference Shares of the Company, to be issued in exchange for the Founders' Shares of the Corporation, being at the rate of £6 and two fully paid-up Preference Shares in exchange for each Founder's Share, which will be thereby extinguished. The price to be paid for the Estates of Messrs. Baring Bros. and Co. and Wangie Oya is £119,000, payable as to £82,000 in cash, which will be provided out of the proceeds of the issue of the Debentures, as to £9,000 in fully paid-up Preference Shares of the Company, and as to the balance, partly in cash and partly in Ordinary Shares credited with £3 per Share paid up.

The Estates purchased from Messrs. Baring Bros. & Co., and Mr. Thring made a profit of over £10,000 for the year ending 30th June, 1891, and owing to the large acreage of Tea which has since come into bearing, the Directors estimate for the present season a profit of £13,000 from these properties, equal to over 10 per cent. on their purchase price, and they confidently anticipate that the other properties which they hope to acquire by means of this issue will give equally satisfactory returns.

The Tea on the Estates, which will be taken over by the Company as from the 1st January, 1892, is for the most part young, and a large proportion of the acreage planted has yet to come into full bearing, hence the output in the future should steadily increase and largely augment the profits. The present depreciation of silver is greatly in favour of the industry, lessening, as it does, the cost of production.

Taking the Forest and Chena portion of the Estates at £2 10s per acre, the cost of the cultivated area which the Company purchases averages under £33 per acre, which compares favourably with prices recently paid for similar land. The average Capital value per acre of the Estates of 27 of the largest Indian Tea Companies registered in London is stated to be over 47 per acre and the average profit earned by such Companies for the year 1890 is returned at 9.89 per cent.

The business of the Company will also comprise advancing money upon Estates and produce, managing estates, and receiving crops for realization on commission, and from their experience of the business the Directors feel confident that favourable opportunities will arise for the profitable employment of the capital now offered for subscription.

The enormous increase in the consumption of Ceylon Tea in the United Kingdom during the last few years is shown by the subjoined figures, supplied by the Ceylon Association in London:

1885. 1886. 1890. 1891.
 3,218,000 lb. 6,245,220 lb. 34,516,469 lb. 51,227,602 lb.
 In the Schedule at foot are given particulars of the acreage cultivation, and elevation of the estates to be acquired. The finest Teas are grown at an elevation of from 30,000 to 6,000 feet, and the areas of such land being very limited, it will at once be apparent that most of the estates are favorably situated.

The following contracts have been entered into:—
 An agreement dated 31st March, 1892, between the Ceylon and Oriental Investment Corporation, Limited, of the one part, and the Company of the other part. An agreement between the Ceylon and Oriental Investment Corporation, Limited, and Messrs. Baring Bros. and Co., contained in letters dated the 11th January, 1892, from the Corporation to Messrs. Baring Bros. & Co., and 15th January, 1892, from Messrs. Baring Bros. & Co. to the Corporation. An agreement dated the 31st March 1892, between the Foreign and Colonial Deben'ture Corporation, Limited, of the one part, and the Company of the other part. An agreement dated 31st March, 1892, between John Huntley Thring of the one part, and the Company of the other part.

The Ceylon and Oriental Investment Corporation, Limited, in carrying on its operations to the present time has entered into various other contracts, of the ordinary business nature, but which it is impossible to enumerate in detail. Applications for Shares will, therefore, be received only on the footing that the applicants have notice of such contracts, and have waived the specification herein of the particulars of such contracts or any further information with regard thereto to which they may be entitled, whether under the 38th section of the Companies Acts, 1867, or otherwise.

The Memorandum and Articles of Association of the Company and the above contracts can be inspected at the Offices of the Solicitors to the Company.

It is intended to apply for a Stock Exchange quotation for the Company's Shares.

Application should be made on the Form accompanying the Prospectus, and sent, with deposit money payable on application to the Company's Bankers.

Prospectuses and Forms of Application may be obtained at the office of the Company or from the Bankers or Solicitors.

SCHEDULE OF ESTATES TO BE ACQUIRED.

Name of Estates.	Average Tea.	Average Coffee.	Acres and Cheena.	Total Acreage	Approximate Elevation. Feet above sea level.
Bonnawatte ...	518	22	78	418	4,500
Le Vallon ...	873	...	66	1779	3,500
Rajabawa ...	283	...	33	316	3,500

	3,944	330	4,076	8,350	...

* The figures represent the Company's one-half share in these estates.

CEYLON TEA.

I had a talk with Mr. Boustead about tea preparation and prospects: he does not approve of tea-drying at a low temperature and as regards the cry for "keeping qualities" in Ceylon tea, a great change has taken place because our teas now pass so quickly either into consumption or to the small distributors, having last year and this ousted China so very widely. A considerable difference in tea

preparation has been effected in some cases by shifting a factory or at any rate withering sheds from a damp hollow to a breezy sunny height. But this refers more especially to the lowcountry. On the other hand I am told of very favorable reports on some Indian teas treated with low temperature drying, and I have been asked to call and see the report of a member of the well-known Mincing Lane Firm, Messrs. W. J. & H. Thompson, which I must do.

FUEL FOR TEA FACTORIES: SOLIDIFIED PETROLEUM BLOCKS.

I am indebted this morning to Mr. Wm. Gow (head of the well-known Broking Firm and tea planter himself), for some important papers with striking testimony to the value of a new patent solidified petroleum as an efficient and useful fuel. Mr. Gow writes:—

'As the supply of a cheap and good fuel for the drying of tea is exercising the minds of so many planters, I am sending your enclosed some particulars I have obtained regarding the new "Solidified Petroleum blocks" that you may bring this fuel to the notice of your friends in Ceylon. I am told that in the form of blocks this fuel is non-explosive and therefore perfectly safe in transit.

Apart from a very large number of favourable press notices, a special circular contains the attested reports on this new process and result of the following gentlemen:—

Sir Edward J. Reed, K.C.N., F.R.S., M.P.; G. J. Snelus, Esq., F.R.S., F.C.S., Bessemer Metallist, &c., past Vice-President Iron and Steel Institute; D. A. Sutherland, Esq., F.I.C., F.C.S., London and Berlin; Boverton Redwood, Esq., F.R.S.E., F.I.C., F.C.S., Technical Adviser to Oil Trade Section of the London Chamber of Commerce; James Dewar, Esq., F.R.S., Pull-riao Professor of Chemistry Royal Institution, Jacksonian Professor of Natural Experimental Philosophy, University of Cambridge; Alfred Blyth, Esq., (late J. & A. Blyth, Engineers, Limehouse).

I will only quote one paragraph from Sir E. J. Reid's report dated Nov. 14th last:—

It is not necessary, I presume, for me to furnish detailed calculations, and estimates of cost and profit, but I may observe that, even when based upon the present limited scale of operations, such calculations and estimates as I have made, show that at the present prices of crude petroleum and of other fuels, a very large, I may say an enormous, margin of economy results in favour of the solidified petroleum in the production of a given amount of heating power. Even this margin will be increased, of course, when the operations assume the proportions of a large manufacture. There is no reason to suppose that the price of crude petroleum will much increase even with a greatly increased demand, because new sources of supply are frequently being discovered. But a very large increase of price might take place, and still leave the solidified petroleum a vast field for economical and highly profitable extension.

Messrs. Snelus and Sutherland's summary runs:—

SUMMARY.—We may summarize the advantages of this process for solidifying petroleum, by saying that it is rapid, extremely simple, and requires no skilled labour. The fuel produced can be handled in much the same way as other solid fuel and a very much greater amount of heat obtained from a given quantity. Its chief advantage over previous experiments in this direction, is that it does not fuse when burnt under the before-mentioned conditions.

There can be no doubt from previous experiments with petroleum as a fuel, that its relative effective heating power it is immensely superior to coal.

We might further add that as it contains no Pyrites it will, therefore, unlike coal, not be liable to spontaneous combustion.

The experiments we witnessed were, of course, on the small scale, but we see no reason to doubt that the

process can be carried out on a large manufacturing scale, when further valuable experience will doubtless be gained. From Messrs. Dewar and Redwood's Report, I take one paragraph:—

In respect to the commercial value of a successful process for the manufacture of a solid Petroleum fuel we may point out that in any localities where the cost of Petroleum in relation to that of other fuel is sufficiently low, such a process should admit of being advantageously carried out on a scale of great magnitude. The enormous extent to which in Russia, and in the United States, liquid fuel is now employed, and the rapidly growing demand for this heating agent for use in metallurgical and other industrial operations as well as for steam raising, conclusively demonstrate that the well-known theoretical superiority of Petroleum over coal as a fuel has been confirmed in practice. Liquid fuel, however, requires for its satisfactory combustion the adoption of special appliances, and in many cases, a solid Petroleum fuel which could be burnt in an ordinary fireplace or furnace, would be preferable or even capable of being used where the other could not. Moreover there are some descriptions of Petroleum occurring in nature in great abundance which from their viscid character are not adapted for transport or use in a liquid state, and if as we see no reason to doubt, the Obenhal process can be applied to such Petroleum it would be possible to utilize the raw material which is at present practically unmarketable. If therefore, by the adoption of the process in question a fuel capable of being transported in the solid form and satisfactorily burnt in furnaces and fireplaces of the usual construction can be economically manufactured from Petroleum the results should of great industrial importance.

Having regard to the presumably enormous undeveloped resources of petroleum in various countries, there does not appear at present to be any reasonable ground for apprehension in respect to future supplies. But, as the matter is one of such special interest to Ceylon Tea Factory owners, I quote the last report in full:—

London, 18th Nov. 1891.

To the Directors of the Solidified Petroleum (Pioneer) Corporation, Ltd.

Gentlemen,—I have had the pleasure of examining at Hackney Wick the Obenhal process of converting crude Petroleum into a solid mass for the purpose of burning it in lieu of coal, and must say that the experiments I witnessed were of a most satisfactory character, more especially in cases where fuel is used to generate steam. It has long been known that by burning Petroleum a greater amount of heat and steam producing power can be obtained than by burning coal, and up to the present time numbers of trials and experiments have been made with a view to introducing this description of fuel, but it has been found that by using Petroleum in a liquid state a certain amount of oxygen has to be combined with it, and in order to do this the Petroleum has to be sprayed in the furnace by means of either a steam or compressed air jet, such process meaning a loss of coal, besides the necessity of having to alter the furnaces into which this Petroleum is sprayed to effect perfect combustion.

In the consolidated system referred to, the crude Petroleum is mixed with a chemical compound equal to about 15 per cent. of its bulk. This is subjected to a moist heat equal to about 210 degrees Fahrenheit, which causes the solid matter to dissolve and amalgamate with the oil. In this state it is subjected to a dry heat of from 400 to 500 degrees Fahrenheit, and commences to solidify; when cooled it is in a pasty state. When in this condition it is placed in a press, pressed into the form of bricks, perfectly solid, and can be transported and used as desired.

The fuel in this form when burned on an ordinary fire grate without any application for spraying presents a bright flame of intense heat without giving off any liquid or smell, and after it has burnt until all the carbon contained has been consumed, it leaves little or no ash.

As a steam generator it is, in my opinion, far superior to the best Welsh coal or patent fuel made from coal and pitch combined, for the following reasons:—
First.—The heat obtained from it is undoubtedly greater (as all who have burnt Petroleum will admit) than that of coal.

Second.—It requires little or no stoking, as its heat comes from the surface and not from the mass.

Third.—There is no refuse left—(it burns itself out)—and consequently there is no clinker or ash to remove from the furnace bars.

Fourth.—It has little deteriorating effect on the fire bars, and can be used in any ordinary furnace.

I have not gone into any detailed calculation as to the comparative cost of this material and coal, but I am sure that at the present price of crude Petroleum and the small cost of solidifying it for steam-generating purposes, it would be much cheaper than coal, and I am of opinion that this method of solidifying Petroleum for its purpose of using it as fuel completely overcomes the difficulties that have hitherto been experienced in burning Petroleum in a fluid state.

Under these circumstances there must be a great future for the fuel in generating steam, both for marine and land purposes, and from the experiments I have witnessed and the observations I have made, I can confidently say that a pound of water can be evaporated by its use more cheaply than the use of coal.—I am, Gentlemen, Yours faithfully.

ALFRED BLYTH.

(Late J. & A. BLYTH, Engineers, Limehouse.)

THE AMSTERDAM CINCHONA AUCTIONS

Amsterdam, March 31.

At today's auctions 2,648 packages of Java bark sold at an average unit of 62 cents, or equal to about 1½d per lb., thus showing no alteration in value upon the last London sales. The following prices were paid:—Manufacturing barks in whole and broken quill and chips 9 to 63 cents (equal to 1½d to 11½d per lb.); ditto root 16 to 43 cents (equal to 3d to 7½d per lb.); druggists' barks, in quill, broken quill, and chips 10 to 133 cents (equal to 1½d to 1s 11½d per lb.); ditto root 11 to 27 cents (equal to 2d to 4½d per lb.). The principal buyers in the order of their purchases were the Anerbach Quinine-works, the Brunswick works, and the Amsterdam factory.—*Chemist and Druggist*.

JAPANESE PERSIMMONS.—The Japanese persimmon, when unripe and not properly cured, is astringent and unpalatable; but when fully ripe, is highly nutritious, luscious, and of delicate flavour. Mr. Ellwood Cooper, of Santa Barbara, Cal., gives the following direction for use: "Place on shelf or side-board or table for ornamentation until it becomes soft. It will shrink somewhat and turn a darker color; if it ripens properly will be uniformly soft in every part—must not be eaten until it is—then peel from the top. The skin is very thin and will leave the pulp readily."—*American Grocer*.

"CANELLA" NOT CINNAMON.—It may be worth while pointing out that the *canella* spoken of in Messrs. Ross and Sinclair's report on Peru is not cinnamon, though in most of the European languages the name for Ceylon's spicy bark is some form of the diminutive of the Latin *canna*, a cane. What the tree referred to in the Peru report is, is shown in the following extract from the Treasury of Botany:—

CANELLA.—The tree yielding Canolla bark has been placed in various natural groups by different writers. The characters of the genus, in brief, are the presence of three bracts, and five sepals; no petals; twenty stamens united below, and having narrow anthers; a one-celled ovary, with two or three pendulous ovules. The tree is a native of the West Indies, and furnishes a pale-orange-coloured bark, with an aromatic odour, which is used as a tonic. The negroes of the West Indies use it as a spice. The plant is frequently grown in botanic gardens.

ON THINGS IN GENERAL, AND TEA IN PARTICULAR.

The thing that's most "in general" is the weather, and about that there's no mistake now, seeing that every afternoon a considerable water-spout bursts over every estate upcountry. Just when we have most flush and want most coolies, the weather stops in and stops works over and over again. But more than enough about the weather.

Now about "Lipton"! I wish we all had estates like "Lipton's" as depicted in the home papers recently to hand. We there see a beautiful lay of land, four Europeans looking after thirteen women plucking, two more weighing leaf, and of course plenty more inside all the factories. This not being "Lipton's" estate, I have to do the work of all that lot single-handed, barring, perhaps half-a-dozen or so—of whom we see only one—whose work it is to attend to the shipping which is only just across the road from the factory. But it's of little use asking "if there is such an estate in Ceylon." Lipton's advertisements appeal to millions while his critics only find a few scores of readers.

Like the man himself, his picture is clever and far-reaching. He has crowded into one picture all that his tea passes through in Ceylon. He has tea fields among the hills, he has a lot of factories on his several places, and he has a lot of superintendents, all told; and his tea is loaded into ships at Colombo, and there are still some elephants in Ceylon, Clever man!

Now, thanks to "L. D.," this oracle has spoken, and has written a letter which defies adverse criticism. Our brother planter Lipton is a clever man, with such a load of business that I wonder he can find time to sleep. What his head "counting-house" will be like when he has opened retail shops all over America "from the Atlantic to the Pacific" cannot be very easily imagined. I think he must be a good friend to Ceylon, while Ceylon continues to produce 60 per cent of coarse rubbish called Pekoe Souchong, Congou, Red Leaf and Dust. Somebody must absorb this stuff so long as all Ceylon is mad enough to flood the market with it. But how much of our good tea does Mr. Lipton meddle with? Let his advertisements answer this question. Here are his selling prices:—

Everywhere:—India and China Blend	1/ a lb.
Ceylon, India and China	1/4 a "
Ceylon and India	1/7 a "
"No Higher Price."	

"No higher price" for what he declares is "the finest tea the world can produce," and he adds "these are planters' prices"!!

Now what do we learn from, and what do we suffer from, these world-wide advertisements? Take his highest-priced tea, that at 1/7 per pound to the consumer. We know that upon this tea he pays

His outgoings for advertisements and all other expenses must, I should say, amount to quite 4d more	4d "	and
if he is satisfied with a profit of	2d "	
this runs it up to	10d	
leaving only a balance of	9d	

as the price paid by him for the "finest" 1/7 tea, Ceylon produces, and for which the planter in Ceylon receives 7 1/2!!—his own price, according to Lipton. My figures for his outgoings and profit are haphazard, I know; but seeing that other retail tea men look for and take 6d a lb. profit, they can't be far wrong.

Is not Lipton, therefore, the greatest enemy the Ceylon planter has? Great in proportion as his influence is world-wide? He posing before the whole world as a Ceylon planter, assures all the consumers in the world that the planter's price for the best tea the world produces is 1/7, free to their doors, through retail dealers. Now we planters in Ceylon—who are not also advertising retail tea-dealers—know that if we got only a fair profit of 2d a lb. on our finest tea no consumer could buy it anywhere under 2/7, even if the retailer did not stick on more.

Owing to over-production all retailers are now getting their profits out of the planter, instead of legitimately out of the consumer. Well, every man for himself as so, small blame to Lipton as a retail tea man, but bad luck to him as a planter for the bad turn he does us in the world.

But, after all, who gives him the opportunity which he is wise enough to seize? Who but the Ceylon planters themselves? Every ounce of rubbishy tea we send into consumption displaces the same amount of what ought to be good tea. People drink their cup of tea as they want it. If good, they are satisfied and pleased; if bad, they evince disgust, but it has served its turn. No tea ought to be procurable under 2s a lb. to the consumer. But, the fact is, our over-production of "pekoe souchong" is killing us. And what is the secret of our flooding the world with this grade of tea? Perhaps I had better whisper the answer to this question, or keep it to myself, seeing the hornets' nests I shall disturb. But bah! who cares? Whence comes our pekoe souchong but from the indigenous and high-class hybrid jät? Isn't that too a beauty? Doesn't it flush? Well, it does, with a vengeance! If you don't look out and get sharp round—coolies or no coolies, weather, or no weather—its "tips" will be half opened and the other half bany; its pekoe leaves a couple of inches long and its pekoo souchong leaves as big as your hand! Compare it with the smaller hardy hybrid and semi-China tree in another field, or not unfrequently growing next to it, producing the very tea we most want, but neglected by the pluckers, because the high-class pekoe souchong leaves of the splendid indigenous is so much easier to pluck and weighs so much more! I will return to this subject.

BROKEN PEKOE.

THE PERUVIAN CORPORATION, LIMITED.

REPORT ON LAND IN PERU SUITABLE FOR AGRICULTURE.

BY ALEXANDER ROSS AND ARTHUR SINCLAIR.

To the Directors of the Peruvian Corporation, Limited. Gentlemen,—In the month of May, 1891 we undertook, at your request, a mission to Peru for the purpose of selecting and reporting upon land suitable for agriculture, but with more especial reference to its fitness for tropical products.

In fulfilment of this mission we left England in the same month of May, arriving in Peru at the latter end of June; and, after a sojourn extending to December, 1891, we returned to England in January, 1892.

We now have the pleasure to submit to you, in the following report, the result of our special explorations, our observations with reference to the adaptability of the country as a field for the investment of capital, and the opinions we have formed in regard to the extremely interesting and boantiful country we have visited.

We propose, in making our report, to deal with the subject under the following heads, viz:—

1. Climate.
2. Soil.
3. Vegetation.
4. Routes taken, with short description of the country passed through.
5. Locality and extent of land selected.
6. Planting, past and present.
7. Transport and outlet.
8. Labour.
9. Peru as a field for Colonization.

CLIMATE.

The climate of Peru may be safely said to be unique, and whether we regard its influence on vegetation or on human health, it is alike remarkable; tropical, yet temperate; variable, yet equable. The influence of the Pacific (Polar) currents on the one hand, and the cool air from the Cordilleras on the other hand, are sufficient to account for this; while the comparative dryness of the atmosphere tends to abundant fruitfulness in the vegetable kingdom, and sufficiently accounts for the marked absence of malarial fever amongst the native inhabitants.

On the coast, where there may be said to be literally no rainfall, the temperature is lower than that of any country, in the same latitude, we have ever visited: and yet there is an absence of the chilling evening breezes so disagreeable in Australia—so deadly in India.

The temperature during our stay of several weeks on the coast—in July and October—rarely varied more than 4 deg. in the 24 hours, viz., 68 deg. to 72 deg.

At a medium altitude of say 10,000 feet above sea level the difference between day and night temperature is of course greater, the thermometer ranging from 70 deg. to 75 deg. during the day and sinking to 50 deg. at night. Still, there is a crispness in the air which renders the climate peculiarly invigorating, and the robust health of the native Chola amply testifies to its salubrity.

On the upper tributaries of the Amazon we approach a more humid and truly tropical climate, still, however, with a general immunity from malaria. Moreover, that insect pest, the *mosquito*—which Providence seems to send as a warning to indicate danger—is very rarely met with, while the land leech so troublesome in India, is never seen here.

The rainfall in the great Montana districts seems ample for all purposes. The nature of the vegetation sufficiently indicates this, though neither here nor elsewhere in Peru has ever any record been kept of the actual amount of rainfall, nor as far as we can ascertain, has such a thing as a rain-gauge ever been introduced into the country. The temperature of the Perené Valley is very much the same as that of Kandy, the central capital of Ceylon, viz., 70° to 85°. The climate, however, is evidently much healthier, and much less windy. No bare brown ridges here indicate the drift of monsoons. Every mountain side is uniformly clothed in majestic trees, above and below all being strikingly calm and silent.

It need scarcely be said that there is a very great variety of soil in Peru, where the geological characteristics are so exceptionally varied; and, as soils partake of the nature of the rocks from the decomposition of which they originate, it may readily be inferred that, in a country so rich in those minerals which form a peculiarly valuable food for plants, the soil is largely impregnated with substances which have a most marked and beneficial effect upon the vegetation.

The prevailing character of the soil on the Montana is a deep rich loam, naturally so rich in humus that all that is required is the simplest tillage. Even on the coast where all appears to be driven sand, cultivation seems at once to change its appearance and character, and no manuring is ever dreamed of.

On the steep mountain slopes, where, up to 12,000 feet, the ancient "Inca" terraces are still to be seen, and where the industrious and healthy "Chola" still grows his splendid wheat, barley and potatoes, the soil is marvellously rich and deep. Six to eight feet of dark mould may frequently be seen on a bed of conglomerate, and again a stratum of dark vegetable soil below.

On the great "Pajonals"—corresponding to our "Patnas" in Ceylon—where the forest abruptly ceases and a treeless sward of rather poor grass supervenes, the soil is a stiff infertile clay. These Pajonals occasionally crop out in the great sea of forest, the extent varying from a few hundred to a thousand acres; and if they do not enhance the intrinsic value of the land, they do add much to the natural beauty of the scenery. The soil of these forest lands is generally speaking, all that could be desired for the tropical products at present most in demand, such as:—Coffee, cocoa, coca, coconut, nutmegs, pepper, cinchona, cinnamon, cardamoms, rice, rubber, sugar cane, sago, tea, tobacco, vanilla, &c. And speaking more particularly of what we have specially examined in the valleys of Pancartambo and Perené, for a distance of from 50 to 60 miles, the nature of the soil is not only unquestionably suitable, but is specially well adapted, for the permanent production of any or all of the products above enumerated.

VEGETATION.

In writing of the vegetation of a country, where the luxuriance is such that Nature in sheer wantonness seems to run riot, it is difficult to keep within the usual bounds of an official report.

There are perhaps few countries where first impressions prove more at fault than in Peru.

Few who sail along the coast could imagine the luxuriance of the Valleys of Chiclayo, Chicama, Cuziavio, Chimbote, or the Rimac. Few who travel by the Central Railway, and look upon the apparently bare brown hills, could conceive the cereal and floral wealth which clothes and adorns them. We were particularly struck with this in climbing a few thousand feet above the Matucana Station, where the hills look so bleak in the distance, yet, where nearly all the most prized flowers of our British gardens cover the rugged ground in their native profusion.

And these modest little plants have their uses beyond the mere gratification of the florist and botanist. In an economic sense their presence sufficiently indicate where other products, more valuable commercially, might also best be grown. At the same time they indicate the altitude more correctly than some of our Aneroids. The *Ageratum*, for instance, so formidable an enemy to us when coffee was at its best in Ceylon, serves here to show a soil suitable for "the fragrant berry," though the locality may not in other respects be convenient. Acres of luxuriant *Heliotrope* scent the air, testifying that—though at a height of over 8,000 feet—we are still safe from frost. The more hardy *Calceolarias* come next, and with the curious *Cuphea*, the red and the blue *Salvia* flourish up to 10,000 feet. After these the chief representative is the blue *Lupine*, beds of which may be seen covering thousands of acres up to 12,000 or 13,000 feet, leaving a few *Sedums*, *Anemones* and *Dandelions*, to dispute the limit of 16,000 feet with the snow.

From 8,000 to 10,000 feet above sea level, wheat, barley and potatoes grow to great perfection, while the oat is a wild weed, giving, when ripe, a yellow tinge to whole mountain ranges where the feet of man never tread.

The cultivation, such as it is here, is laborious enough, and is hardly suited to our European ideas of husbandry. To scramble over the miles of precipitous paths leading to these terraced fields of a few yards in breadth seems a day's work in itself; but the merest scratch in the shape of ploughing is sufficient, and such is the richness of the soil that no manuring is ever necessary to grow heavy crops of grain and excellent potatoes, oca (*oxalis*), &c. Europe has already been indebted to Peru for many valuable acquisitions to the field and garden, and there is still to be introduced a potato, unquestionably superior as a food to anything of the kind now grown in Britain.

From 12,000 to 14,000 feet altitude barley continues to grow luxuriantly, but ceases to mature its grain.

The *Alfalfa* as it is here called, grown so extensively from the coast up to and over 10,000 feet, is really a native of England. The *Lucerne* (*Medicago Sativa*), so well known to our forefathers, has here in Peru become the most productive and nutritious of all fodders for cattle. On the mountain plateau, which extends for hundreds of miles, the ruins seem somewhat fitful and uncertain, but not more so than in most parts of Australia; and it is curious to note how kindly Australian trees, chiefly the *Eucalypti*, take to this climate, growing with great luxuriance wherever planted. Amongst the rest of the somewhat scanty vegetation here, we observed the *Elder*, and by the watercourses the *Alder*, both natives of Britain. Again, amongst the native trees a very beautiful and useful evergreen willow (*Salix Humboldtiana*) abounds, a tree that would be a great acquisition to Ceylon, North Burma, India, &c. We will now pass over these rather grassy lands, on the eastern side of the Cordilleras (upon which llamas, alpacas, vicuñas and sheep seem to find ample pasturage), and after a journey of about 60 miles N.E. from Tarua, plunge at once into the primeval forest, at an altitude of 4,000 feet.

The first thing that struck us was the marvellous variety of the gigantic trees. In most other countries large groups of the same family are found growing up together; such as Pines in North America, Gums in Australia, &c. Here diversity is the rule, and seldom

do we find two of the same kind growing in company, —nature delighting rather in variety and contrasts,—one tree upright as an Arceuthobium, another sloping over a chasm; one with bark smooth as ivory, the next prickly as "Acacia horrida." Exceptions there are, and one might be seen on most river banks, viz., the Balsam wood (*Ochroma piscatorum*), as if providently placed there for the natives, who invariably use its remarkably light wood for their rafts. The *Ochroma* has a cotton-like fruit which might be used for stuffing beds, &c.

The graceful ivory palm (*Phytelephas*), may also be seen in small groups, indicating the very richest spots of soil. Near to this may be found a solitary *Cecropia* (*Theobroma*) 30 to 40 inches in circumference, and rising to the mature height of 50 feet. Coffee of course is not found wild here, but at intervals we came upon gigantic specimens of the *Cinchona*, both *Calisaya* and *Succirubra*, 6 feet in circumference. The *Walnut of Peru* is frequently seen in the Poroné Valley, growing to a height of 60 to 70 feet. Satinwood there is also, but not the *Satinwood of Ceylon* (*Chloroxylon*); for though the wood looks similar, the family (*Ebenacea*) is in no way related to our Ceylon tree. The indigenous *Coca* as an undergrowth we rarely came across, except in semi-cultivated patches. Gigantic cottons, the *Scrub Pine* (*Carludovicia*) from which the famous Panama hat is made, the grand scarlet flowering *Erythrina*, and another tall and brilliant yellow flowering tree—probably the *Laburnum of Peru*—add much to the beauty of the scene. Many other leguminous plants we also noted, particularly *Calliandra* and *Chloria*.

Innumerable *Orchids*, mosses and ferns sufficiently indicated the humid nature of the climate and fully satisfied us as to the rainfall.

Probably the chief distinguishing feature in Peruvian vegetation is that it is an essentially flowering and fruit-bearing vegetation, rather than the excessive leaf-producing which so distinguishes the luxuriant greenery on the Island of Ceylon. Peru undoubtedly possesses a richer soil and a climate more favourable to fruit bearing; while, compared with the massiveness and grandeur of the Trans-Andean forest monarchs, the jungles of Ceylon are somewhat diminutive. A few plants we missed; the beautiful and useful yellow *Bamboo* is not there, nor are the *Palmyra*, *Talipot* and *Coconut Palms*. The *Jak* and *Breadfruit trees* might also be introduced with great advantage. The cultivated grasses of the East, the *Guinea* and *Mauritius grass*, are here already, but as a nutritious fodder they cannot be compared with the "Alfalfa" (*Lucerne*). Of the leaf products, perhaps none are destined to become more important than the *Coca* (*Erythroxylon*), which is bound to increase in value commercially as its undoubted virtues become better known. The land we have specially selected on the Poroné, as hereafter shown, may be said to be the native home of this invaluable plant, and as we doubt if it can be grown in any other part of the world with equal success we would strongly recommend its being planted out on an extensive scale to meet the growing demand.

The various kinds of Rubber found here might also be cultivated, or rather planted out, on a large scale with much profit and at little cost.

ROUTES TAKEN, WITH SHORT DESCRIPTION OF THE COUNTRY PASSED THROUGH.

Having thus indicated the nature of the climate, soil, and vegetation of the country we visited, it may be of some interest, before dealing specifically with the land selected, to state shortly the routes taken in our search after land suitable for the purposes of tropical agriculture, and, as briefly, to describe the main features of the districts we passed through.

The western slopes of the Andean range extend, in the valley of the Rimac, from Callao, the port of our arrival, to Chivila, the temporary terminus of the Central railway.

The altitude of Chivila, at which the approximate limit of cultivation is reached, is 12,215 feet above sea level.

From the sea the valley is wide and flat, but it narrows beyond Lima, and becomes steeper and somewhat rugged near Chosica, when the hills lose upon

the plain. The valley is highly cultivated between Lima and Chosica, and at Chosica tillage of the terraces, at the base of and along the mountain slopes, begins.

After leaving Chivila, beyond Casapalca, the Cordillera is encountered and crossed. The country—especially the first twelve or fifteen miles—is wild and rugged, producing on the slopes and in the valleys only the shortest grass, affording but scanty food for the llamas and deerkeys proceeding to and returning from Chivila and the railway, with ores, produce and merchandise.

From the summit, near Galera, the country becomes more undulating, and, as Pucara and Paclachaca are reached, it is more suited for grazing. Between Paclachaca and Oroya lies a fine grazing country, along which sheep in large numbers everywhere find abundant pasture.

Oroya, a hamlet consisting of an hotel or hostelry and a few huts, is at the point where, by a wire suspension bridge, the bridge road leading to Tarma, Janja, &c., crosses the Oroya river. Thence about a mile and a-half out, the roads to these towns diverge—for Tarma to the left, and for Janja, Huancayo, &c., to the right. The former road ascends abruptly to over 16,000 feet and, crossing the Cordillera, descends towards Tarma by a rough and steep path leading through poplars and thriving villages. Near that town the valley widens and becomes a scene of busy agricultural industry. The road to Janja continues through bold, undulating, grazing country, ranging from 12,000 to 15,000 feet altitude, till, from near Acola, the whole area appears terraced and cultivated, the soil being everywhere exceedingly rich and friable.

Tarma is a town of importance, having a population of about 6,000, engaged chiefly in trading. There are good hotels and schools, and a weekly market, to which the produce of the surrounding country is brought. It is the centre of a considerable agricultural district, comprising a great portion of the terraces and slopes of the surrounding hills; and from it roads lead to Janja, Cerro de Pasco, Chanchamayo and other places.

The country along the above route is mountainous and the slopes are steep, but where possible they are terraced and cultivated. A few miles below Paclachaca, however, agriculture ceases, and the old bridge road—for which a fine new road at a gradient of 1 in 20, and about 9 feet wide is being substituted—treads along the shoulder of a precipitous gorge, through which the Chanchamayo river, in a series of tumbling rapids, finds a tortuous course.

Huacapistana, an hostelry, and Pando Azuara, near the upper limit of tropical vegetation, are on the river bank, in a deep and narrow ravine. From the latter place to Chalwapuku and Naranjal, (the commencement of the Chanchamayo Valley, where we first saw the cultivation of sugar-cane) the hills recede towards Port San Ramon—near to which the road to Viteo turns off to the right. The mountains close in again near and beyond La Merced, a thriving village, having two hotels, some good shops and stores, and situated in the centre of a sugar-cane and coffee growing district, the cultivated portion of which is now confined chiefly to the river banks.

The valley is limited in area, and is bounded on all sides, especially on the south, by high and somewhat precipitous hills and ranges.

From the Rio Blanco, near the eastern boundary of Chanchamayo, the road trends along the left bank of the Chanchamayo River to its junction at Port Wertheimann with the Rio Paucartambo. The whole country along this road, excepting two or three small "chacras," or gardens belonging to natives, is uncultivated; but on the right bank of the Chanchamayo, which is rocky and bare, there is forest only at the base of the hills.

From Port Wertheimann, where there is a fine flat of limited extent, to San Luis de Scharro, is a continuation of country as above described. Opposite the latter place, which consists of a convent and a few huts, begins the western boundary of the lands selected by us along the valley of the Rio Perené,

These lands ranging in altitude from 6,000 feet to under 1,000 feet above sea level, are densely wooded, save where broken by pajonals (grassy areas), and abound in valuable and magnificent timber trees. The lay is chiefly undulating, though here and there precipitous, but it is also in parts flat and easy of irrigation.

The Rio Perené which intersects longitudinally our selection, is a large river into which from north and south streams of some volume flow. The land selected extends to 20 kilometres, or 12½ miles, north and south of the river and from Port Wertheim eastward to the terminus of navigation near the confluence of the Perené with the Enc, with a like distance on both shores of the Enc from its mouth for a distance of 20 kilometres ascending. Port Wertheim is situated at the confluence of the Rio Pancartambo with the Chanchamayo, where these rivers become the Rio Perené.

The road from Tarma to Cerro de Pasco is the same, for six miles, as the route from Tarma to Chanchamayo. At Acobamba it turns to the left or north through an easy lying and fertile valley of no great breadth. Near Cacas steep ascents—first through a rocky and precipitous gorge, and then over the Puno—have to be surmounted.

From the summit the country opens out into a flat grazing plain of great extent, with some undulations at the far end, reaching Cerro de Pasco, through Junin and Carhuamayo, whence via Ninencaca a road branches off towards Huancabamba and Pozuzo.

Cerro de Pasco, the centre of a great silver mining industry, is cold and bleak. It is situated on a low terrace on the shoulder of a high slope of the Cordillera, and is partly surrounded on the east and north by rocky mountain ranges. The road towards Huancayo, after crossing for a short distance the plain in which are the silver mines, leads past the source of the Rio Huallaga, down a steep, wild, rugged gorge, and thence through more undulating and richly cultivated ground to Huarriaca, where there is a comfortable hostelry.

From the latter place to Ambo, after hugging the river, the road is carried along the face of a series of precipitous mountains, down to the Huallaga, hundreds of feet below. Before reaching Ambo we saw the first coffee field.

Huancayo is reached from Ambo by a flat wide road, which, at its northern end, runs through a fine avenue of Eucalypti and other stately trees, and the route of which lies near to the Huallaga, intersecting a richly cultivated valley. The hills on either side are bare and dry, the only growth visible being large Cacti. All cultivation is carried on by means of irrigation. Rain falls only at periods during the rainy season, from November to May. There are no forest trees, nor is there any forest nearer to Huancayo than 15 leagues or 45 miles.

Returning via Cerro de Pasco, the road leads through the Pampa of Junin towards and around the lake of that name. The Pampa is very extensive and the lake is a magnificent sheet of water. Around the lake graze herds of cattle and sheep, and there are many kinds of water-fowl. The road via Incahuasi and San Blas passes through a great extent of Puna, at varying altitudes, to Baños, where are hot springs and an hostelry. The latter place is situated in a fine grazing country, and close to streams about which their is an abundance of wild ducks, geese and other wild fowl.

The plain connecting Jauja with Huancayo is 30 to 40 miles long, by about ten in breadth, including the raised tableland on the west. From Huarripampa the Oroya river intersects the plain, which it, in parts, overflows. Numerous towns and villages are situated throughout the valley, which possesses rich and fertile soil, an excellent climate and an abundant population. Jauja, Concepcion, and Huancayo are towns of some size and importance, and are the centres of considerable trade as well as the resort of invalids suffering from pulmonary complaints. At all these towns there are good hotels. Nearly half-way between Jauja and Huancayo, and situated at the foot of the steep hills up and over which leads the road to Comas and Andamarca, is the Convent of Ocopa, the chief seat of the Franciscan brotherhood.

The road to Comas ascends to 15,000 feet above sea level, at which altitude, down to 12,000 feet, the greater portion of it lies. Comas is a small town or village situated on a saddle between two deep valleys. Agriculture is the only pursuit of the inhabitants who till their ground entirely by means of wooden implements of very primitive construction. The country is exceedingly rough and wild, and is bare of anything but grass. It is essentially a grazing country where not too high; but for the most part it is cold and bleak, with hardly a shelter or the possibility of procuring food for man or beast.

Malapa, a small village at 8,100 feet, and Andamarca, likewise of small extent, at 8,300 feet altitude, situated about two miles apart, in a deep recess among precipitous mountains. Neither these villages nor the country around have any attractions excepting the wild grandeur of the rocky and snow-clad ranges—through which the bridge track threads its way—and their utter isolation and romantic surroundings.

LOCALITY AND EXTENT OF LAND SELECTED.

The best available land within easy distance of the Oroya Railway, and suitable for Coffee, Cacao and other tropical products, we found to be in the Perené Valley, about lat 11 S., long. 75 W., altitude from 4,300 down to 1,050 feet above sea level. The area might be indefinitely extended from Pangoa on the one side, to Pozuzo on the other; but taking only 20 kilometres on each side of the River Perené—traversed by us for 40 miles—we have about 1½ million acres of almost unbroken forest, of inexhaustible fertility, and all, as far as we could judge, admirably adapted for the successful cultivation of every known tropical product. It seems but a small patch from the vast reserves of this country; yet it is capable of producing more coffee than the whole Eastern world at present supplies; and it will be remembered that when Ceylon was the third coffee producing country, it had only 200,000 acres in cultivation, or about one-sixth of the extent selected in the Perené Valley.

Specifically our examination of the land commenced where the "Eñeno" rivulet falls into the Perené. The altitude is 1,900 feet, and the rainfall is evidently ample. The land, rising from the river on the north side, is somewhat steep, but with its rich open sub-soil is specially well adapted for coffee; and a few thousand acres might be planted here at an altitude of from 1,900 feet at the river up to 3,500 or 4,000 feet on the ridge. Immediately opposite—on the south side of the river—there are a few hundred acres of rich flat land, suitable for any tropical product; but here, as a rule, the north side is decidedly the best. Pursuing our journey downwards—the river being at all times quite navigable—we were greatly delighted with the ever-changing yet always enchanting scenery, the rich but not over-dense, undergrowth, the gigantic trees, covered and festooned with creepers and parasites, all indicating a forcing climate and virgin soil of amazing fertility. About three miles downwards we stopped to examine a salt spring, evidently indicating a salt mine at no great distance. From the fifth to the sixth mile a grassy ridge or "pajonal" rises up to about 4,000 feet, in extent probably about 500 acres—a good point from which to view the surrounding forest—while on the south side of the river there are numerous patches of similar grassy land. Beyond this there is a vast unbroken tract of the richest forest, from which occasional rivulets fall into the Perené.

The largest tributaries received by the Perené come from the south side. "The Pichana," about 16 miles from our starting point, is a permanent stream of considerable volume, sufficient as a motive power for any ordinary purpose for which it may be required, while about 20 miles farther down, the "Ipuki," about equal to the Tweed in volume, adds palpably to the depth and force of the Perené. From the 15th to the 20th mile there is a large tract of flat alluvia land on the north side of the river, probably extending to 1,500 or 2,000 acres, admirably adapted for rice culture, for sugar cane, cacao, or for nurseries

of coffee and cacao; and when planting is decided upon this will probably form the first scene of operations. From this point onwards to "the Cascades" the current of the river averages about four miles per hour. On either side the forest increases in density and continues equally fit to produce inexhaustible supplies of *cocoa*, *coffee canela* and *rubber*. Many of the gum trees such as *Acacia Arabica*—the produce of which is becoming so scarce—would also find here a congenial home. Our balsas (rafts) now began to glide more rapidly onwards; indeed, we came upon the Cascades—more properly *rapids*—rather unexpectedly, and had suddenly to call a halt, which we effected with some difficulty. None of our so-called guides having ever been here before, they were as much taken by surprise as ourselves.

Our aneroids registered 1,050 feet above sea level, and the distance from the mouth to the Eueno, from which we started, we estimated to be about 40 miles. All around these rapids we found the same land forest to partake much of the same characteristics as for the last ten miles, only that now both sides of the river seemed to be equally good.

Perhaps the one great advantage possessed by this land in the Perene Valley is the fact that it lies within reasonable distance of either outlet. Chanchamayo, Vicos, or Huancayo, may be conveniently situated for the Oroya railway, but in the case of a temporary breakdown would be comparatively helpless. Land nearer to the Ucayali, on the other hand, would not for many years to come participate in the undoubted advantages of railway communication and if planting is to be done on a large scale—*as, if done at all, it ought to be*—the question of a double outlet ought to be seriously weighed. Hitherto this, the greatest reserve in the world, has been merely sending samples of its indigenous products. It is now high time that planting enterprise should be undertaken methodically, and on purely commercial principles.

PLANTING, PAST AND PRESENT.

If one is to judge from the principal planting district—Chanchamayo—there has really never at any time been the remotest approach to methodical coffee planting in Peru. The land, a mere fringe along the river side, had been selected without much discrimination, some 20 years ago, and planted in the first place with indigo, which grew well, and is still a thriving weed; but the proprietors not having taken the precaution to procure managers acquainted with the preparation of the article, the enterprise collapsed.

Coffee was next tried under similar conditions, and the plants seem to have thriven as they seldom thrive in the East, even with greater care; but inasmuch as the bean was not prepared in a way suited for the European market, and the local prices were not sufficient to repay production and transport, this too had to be abandoned. Only a few scattered patches now remain, sufficient, however, to show the capabilities of the soil and climate. The crop we saw on many of these uncultivated trees would not be estimated by any competent coffee planter at less than 20 cwt. per acre. And yet the export from the whole district is insignificant—variously estimated as from 1,500 cwt. to 2,000 cwt.—a quantity which might be produced by 200 acres properly cultivated.

Sugar-cane now absorbs the attention of the planter here, although not an ounce of sugar is manufactured, the local demand for rum being such as to exceed the present possibilities of supply. It may be conceded, that no previous venture ever paid the Chanchamayo planters so well; but the effect of the product upon the natives may well be imagined, and can scarcely fail to be disastrous upon the local labour supply.

The district of *Huancayo*—so famous for the quality of its coffee—was a disappointment to us, the extent under this crop being quite insignificant; and all the land around the township was said to be in private hands. On some of the principal haciendas, the extent in coffee is only from 2 to 3 acres, which, though bearing enormous crops, gives a total export of under 1,500 cwt. Unlike Chanchamayo, every plant has to be irrigated here; and it may be remarked

that, with irrigation, coffee could be grown almost anywhere in Peru, under 7,500 feet of altitude. In the neighbourhood of Lima, for instance, we have seen coffee growing, with no particular care but with a sufficient supply of water, bearing as heavily and looking as healthy as the best we ever saw any where, and some of the finest samples we have seen came from the west side of the Andes, about 100 miles north-east of Salaverry.

The *Sugar Estates* on the coast, particularly in the valleys of *Chicama* and *Chilcayo* are exceedingly well cultivated, and even at recent low prices leave an ample margin of profit. Some admirably managed properties we have the best authority for stating, yielded an annual net profit of over £20,000 during the past three years; and this grand industry might be extended indefinitely for hundreds of miles along the seaboard of Peru.

TRANSPORT AND OUTLET.

The means of transport from the lands allotted to the Corporation are in course of being made easy; and though objection may be taken to the cost of transport as compared with that prevailing elsewhere, the difference need be no barrier to a close and successful competition with better known countries, whose interests it may affect.

Apart from this, Peru offers the advantage of a large local demand certain to increase, proximity to North and South American centres of trade, and facilities of transport thither; and there are in addition the usual European and Asiatic markets, to which vessels trading to these markets would necessarily carry its products.

Whatever may be the requirements of the Perene Valley in future years, when transport will be necessary for millions of cwt. annually, there can be no doubt that for present purposes a light railway to Oroya would be most suitable, though for future exigencies it would only be courting misfortune to have such an important district confined to one outlet.

The cost of extending the railway would be comparatively little; the present road from Tarma to Chanchamayo might be largely utilized for the purpose, and from thence, through an undulating country with abundance of timber, 30 miles of rail would not be a serious undertaking. The railway would also tap such labour supplies as the country affords.

The other, or alternative outlet, via the Amazon, might be effectually secured by blasting the rocks in the rapids or cutting around them a road, the highest estimate of which does not exceed a length of 12 miles. With these two outlets the district would only be sufficiently supplied; for while it would be exceedingly inconvenient to be cut off from the capital of the country and the means of drawing supplies from the Pacific side, it would at the same time be hazardous to be entirely dependant upon one thread of railway.

At present, rates of transport by means of pack animals are prohibitory. But with the extension of the railway to Oroya within a few months, the speedy completion of the road from Tarma to Chanchamayo, and the substitution of roads at easy gradients for those now used between Oroya and Tarma (a distance of about 20 miles), La Merced and Port Werthenan (about 12 miles), all what we indicate can be accomplished.

LABOUR.

Of the greatest importance to the future of Peru is the speedy, ample and successful introduction of labour from distant countries.

The Chola inhabitants of the hills, and the mixed Indians of the towns and villages, who with the Chinese on the coast haciendas, at present constitute the supply, are insufficient of the wants which any extension of agricultural industry would create. The former, living as they do within reach of their homes, cannot be depended upon for the efficient and economical working of plantations. Advances are made to them, amounting to their pay for periods of three months. These advances they work off after which they are free to, and often do, leave for

their villages. Frequently the engagement is renewed with advances, to be worked off as before. No system of agriculture, more especially tropical agriculture can be carried on successfully if dependant for its labour upon a supply so fitful and so scanty. It is of importance, therefore, to introduce a class of emigrants who would have neither the desire to leave, nor the means of leaving, their employment, excepting at fixed periods of some duration and under definite engagements. On the coast there are still numbers of Chinese emigrants whose engagements date back many years. These however, are dying out; they are not being replaced, and it will become a matter of serious consequence to all employers of labour should there not, at some early date, be preparations made to supplement them, as well as to arrange for an increasing supply from China or India.

Chinese we found to be excellent labourers if kept away from centres of population. As it is not proposed to take them to or keep them near any town or village, but to settle them where in the interior agricultural work will engage their time and attention, no hesitation should be felt in regard to their introduction in large numbers, or in making arrangements for a constant supply of a people whose characteristics are excessive thrift and untiring industry; by whom too, the benefits accruing from these are so keenly appreciated.

Indian, i. e., Hindoo or Tamil coolie laborers, and their families, if introduced, would also prove a source of wealth to the country, improving as well their own condition as that of their employers.

Of the Tamils we have long personal experience, and we are convinced, that with their aid, and under the skilled direction to those accustomed to work them the fine slopes of the Perene, and any other part of Peru where tropical agriculture might be tried, would speedily be rendered productive and valuable.

Unquestionably numbers would elect to settle in a country, and amid surroundings, so congenial to their wants and desires.

There can be no objection on the part of employers to give such guarantees as would both satisfy the Government of India, and secure to the coolie all the benefits of profitable, healthy and constant employment in country, the climate of which—from our Ceylon experience we are assured of it—is so free from malaria and in all respects so suitable to his mode of life.

PERU AS A FIELD FOR COLONIZATION.

This land of the ancient Inca has such vast undeveloped resources, at altitudes and temperatures so varied, that people from every known climate might here find a congenial home; and we cannot conceive of any healthier, more interesting or profitable occupation for European agriculturists, with a little capital, than might be found on the borders of the great grassy pampas, at an altitude of 4,000 feet and upwards, where a mixed cultivation might be introduced, including cereals, potatoes and other vegetables, around the homesteads, with a field of coffee or coca below, all interesting and profitable to the grower.

It is only to be regretted that so little is known in Lima of these localities, and that the facilities for approaching them have hitherto been so indifferent.

With the opening of the Oroya railway, however, all this will be changed, and the prospect of successful colonization rendered such as was never before possible in Peru.

For trained planters, with a command of labour, and judiciously backed by capitalists, we believe, there is not in the wide world a better opening than in the upper valleys of the Amazon and its Peruvian tributaries.

We are, Gentlemen,

Your obedient Servants,

ALEXANDER ROSS;

ARTHUR SINCLAIR.

POULTRY FARMING IN INDIA.

By A LADY CONTRIBUTOR.

So many people who have tried poultry farming out here have told me that, leaving time and trouble out of the question, it never pays and is, in most cases, a dead loss. In the rearing and selling of ordinary

fowls only, I most certainly agree with them: as a native can always undersell a European, especially in livestock, as natives seldom give their animals a regular meal. In the case of chickens, a few grains of boiled rice and some crumbs of *chapati* left from his own meal are thrown to them and they are left to find what they can for themselves. A native can afford to sell a roast fowl from four to six annas, where we should be sorry to part with one for fourteen annas or a rupee. So it is really almost impossible for us to compete with them. The only way in which to make a poultry farm pay, and I find it pays me handsomely, is to keep everything, fowls, guinea-fowls, ducks, geese, turkeys and pigeons. For those who go in for gardening on a large scale this is not feasible, unless their grounds are unusually large, and then both the kitchen and flower, garden should be hedged in or railed off in some way, otherwise the fowls, ducks and more especially, guinea-fowls make fearful havoc in it. The only two ways I know of preventing this are, if you have a large compound, to make the fowl-house in the opposite direction of the gardens and at a good distance, or the better plan is to keep a small boy and make him guard the entrance to the garden.

My plan of housing the poultry is to make a large rough mud house, have it scraped and smoothed down and white-washed inside and out, with a tiled roof; the house is divided into six separate rooms with a door and window opposite each other in every room, excepting in the pigeon room, which has only one door; every door has a trap so that the poultry can go in and out at will during the day.

In the first room I put all the cocks and hens besides the cockerels and poulets over two months old at night giving them perches and boxes and not overcrowding them. The second room is given to the ducks, geese and guinea-fowls; perches are put up for the latter and straw placed on the floor for the two former, as they generally lay at night or very early in the morning. The third house belongs to the turkeys, and the fourth to the pigeons, in the wall of which I have large holes made in which they lay and bring up their young. The fifth room is plank off into four compartments which I shall call A, B, C, and D, for convenience. In A, all the chickens under two months old are kept from sixty to seventy and sometimes more. In B, I put a goose who is given all the goslings, which she readily takes. In C, I place a couple of large boxes with high sides perforated with small holes into which I put all the ducklings, D, belongs to the guinea-chicks with their adopted mothers—a couple or three pens (not guinea fowls). The sixth room is kept for all and only setting hens. Sometimes twenty or more boxes are placed on the floor and baskets hung firmly against the sides of the wall; in those they sit and hatch their eggs.

Every morning at half-past five o'clock all the doors of the fowl-house are opened, and all the poultry dare let out, fed, and allowed to wander over the grounds till evening, a small boy looking after all the different broods of chickens, ducklings, &c. These are fed three times a day on good sound crushed grain-greens and table scraps with a little meat twice a week, and are locked up from 11 a.m. to 2 p.m. during the hour of the day, while the boy in charge has his food and a rest. All the six rooms are carefully swept and thoroughly cleaned every morning, and a layer of fresh ashes put into each. The native servants each getting an old korosaino tin for collecting them in, so that there is always a large supply of ashes in hand. The sitting hens are given plenty of good sound grain and fresh water every morning, and are then allowed to roam about for an hour after which they are brought back, and locked up till the next morning, being fed once in twenty-four hours, and having one hour's exercise when they generally take their dust baths. Ducklings are considered difficult to rear, but I find mine do very well, they are fed on *chapati* soaked in water, hard boiled duck's eggs with a little boiled rice of the cheapest kind, till they are a fortnight old, when they get bran, crushed grain and potato peelings.

My guinea chicks are fed on *tangen*, a kind of millet and white ants till they are a fortnight old, and then they are fed on *bajra*, and after a little time will eat almost any grain and a little meat. Goslings I have only been able to rear on *tangen*, letting the mother goose have them all day with her in the river and seeing them fed every morning and evening. Turkey chicks are given bread and milk or rice and milk at first, and then, later on, bran, onions and grain with a little meat or milk. The rest of the poultry are fed twice a day on peas, Indian corn, unhusked rice and wheat sometimes mixed and sometimes in turn, as they tire of the same thing every day.

In conclusion, I may add that my notes though hurried, may be serviceable to those who live in the district, where butcher's meat is not to be had, and a variety of food is very necessary and beneficial, and the only things procurable in the bazaar are the ordinary tasteless, the fleshless *moorhicc*, occasionally wild duck, and quail, and the everlasting goat. Poultry farming does pay, as anyone, who will try my plan for a year or two, will find very few deaths occurring. In fact I may say so far all the deaths in my farmyard have been accidental such as ducklings being carried off by kites, fowls being torn by pariahs, &c., and these have been few and far between."—*Indian Planters' Gazette*.

ALLSPICE.

The term "all spice," like many other trade terms, is merely a conventional one; it has probably been applied to the small brown globular berries because of their curious compound flavour, which is thought to comprehend that of cloves, cinnamon, and nutmeg. The so-called "allspice" is really the fruit of the *Eugenia pimenta*, a member of the natural order of *Myrtaceae*. The tree is a beautiful ever-green, growing often as high as thirty feet, and it can be conveniently described as a species of large myrtle. The natural habitat of the *Eugenia pimenta* is the West Indies, but it is now cultivated almost exclusively in the island of Jamaica, where it seems to thrive without much attention. If a plantation be near a town it usually forms a favourite resort for the inhabitants, who love to saunter along the "pimento walks." There are nearly ten thousand acres of pimento trees under cultivation in Jamaica. After flowering, small racemes or bunches of tiny green berries appear upon the branches, and before they reach maturity they are picked, and spread out in the sun to dry. Some growers prefer to kiln-dry their produce. If the berries were allowed to ripen before being gathered, much of the characteristic flavour would be lost, for the essential oil, which chiefly resides in the shell, is most abundant in the unripe state. After a few days' exposure to the sub-tropical sun the berries are sufficiently dried, and their green colour has changed to a characteristic clove-brown; they are then stripped from their stalks and packed for export. The berries chiefly consist of a woody shell containing a kernel, and in the shell are tiny spaces which serve as receptacles for the essential oil.

The history of allspice, like that of most spices, is involved in much that is merely legendary. A very high value was set upon species by the ancients, which was due, perhaps, not to their being of any remarkably good use, but rather to their being difficult to procure, for means of communication, especially with tropical countries, were limited and dangerous. The old Spanish navigators gave the name *pimenta* to the berries which we now call allspice, because they thought they resembled in shape and pungency of taste the pepper berries with which they were already familiar. Allspice appears to have been first mentioned by an old chronicler named Clusius, who wrote a good deal in the early part of the seventeenth century. We first hear of its appearance in England from Parkinson, who informs us that at about the same time it was "being

obtruded for amomum, so that some more audacious than wise put it in their compositions instead of the right." This amomum of which Parkinson speaks is probably the round cardamom seed. A writer in the latter part of the seventeenth century called Ray is the first who speaks of Jamaica as the source of allspice. He also tells us that it was used as a condiment like pepper, and commonly known by the name of "sweet-scented Jamaica pepper." It was during the latter part of the eighteenth century and especially, the early part of the current century that allspice developed into such an important commodity.

In order to recognise any article that is liable to adulteration, it is important to be familiar with the microscope structure. Familiarity with appearances under the microscope can of course be best acquired by actual study, but here are the most important features. A section of the husk exhibits cells filled with essential oil, and stellate cells embedded in cellular tissue with spiral vessels and bundles of woody fibres. Membranes separate the shell from the inner kernel, and in these the microscopist will notice elongated and angular cells; one of these membranes contains cells of a deep port-wine colour which is very characteristic. Starch granules will chiefly be found in the kernel, and mixed up with them will be noticed angular and transparent cells of characteristic appearance. The chemical composition of allspice, strangely enough, has not been thoroughly investigated; it is difficult to obtain access to any very recent complete analyses. In many respects it seems to resemble the composition of cloves. The berries contain a volatile oil, which contributes the peculiar flavour; tannin, which accounts for their slightly astringent taste; and starch, which is unimportant for flavouring purposes. Dragendorff states that he has isolated an alkaloid from allspice which has an odour resembling that of conino; now this substance smells like nothing so much as the odour of nico, so that it is a lucky thing for allspice that it contains so minute a quantity. The essential oil is the most important constituent of the spice. Pereira informs us that it really consists of two oils; these he distinguished as light oil of pimento, which is a hydro-carbon, and heavy oil of pimento, which is a substance possessing acid properties. The oil chiefly resides in the shell, and is best extracted by distillation with water. The yield of pimento oil is 4.37 per cent. of the total weight of the seed, according to the authority of Whipple.

Amongst other scientists, Olser and Gladstone have contributed to our knowledge of the chemistry of the fruit of pimento, but still there is room for more information. Perhaps the reason of our comparatively imperfect knowledge of the chemistry of allspice exists in the fact that it is not much adulterated. If it had been subject to much adulteration, it is certain that analysis would have found it necessary to thoroughly investigate its constitution. When the spice is in a ground condition we may possibly find starch, flour, or other fine cereal matters mixed with it. The percentage of starch is small in the natural spice, so that this trick would easily be discovered. Ground allspice is well known as an important ingredient of "mixed spice." Of course, such a promiscuous name as "mixed spice" may cover a multitude of ingredients, but it really ought only to represent a mixture of ground allspice, ginger, cloves, and cinnamon. Mixed spice is rarely adulterated with anything but floury matters. Of the "substitutes" for allspice which are sometimes mixed in with the berries there are only the *Pimento acris* berries, those of the bay-berry tree, and those of the *Pimenta di Tabasco*, or Mexican spice. These berries are somewhat larger than those of true allspice, and by anyone who knows how to examine a sample, ought at once to be recognised from their different external characteristics. The consumption of allspice in Europe and the United States has considerably increased during the past few years; being inexpensive and possessing a very agreeable flavour, the spice forms a popular ingredient for domestic cookery.—*Grocer*.

MEXICO AS A COFFEE GROWER.

ONE of the best authorities in the world on coffee and coffee raising, says *American Export and Finance*, is Mr. Joseph M. Walsh, the author of an able and exhaustive work on the subject and himself an expert dealer in coffees in Philadelphia. What he has to say about the suitability of Mexico for coffee cultivation, and about the quality of the Mexican grown coffee, is therefore entitled to the highest credence and the greatest consideration. He gives his views in the following letter:—

"Philadelphia, February 6, 1890.—There is no field for capital that I know of at the present moment that promises such large returns as that of the overlooked and much rejected one of coffee cultivation. Among my reasons for this statement may be mentioned its high market price now, and the fact that it costs no more to grow it than when it sold for one-half its present figures. If planters made money when the selling price ranged from 8c. to 10c.—and it is generally admitted that they did make money—how much more can be made, do you suppose, at 100 per cent advances? The area of coffee cultivation must be increased to meet that increasing demand for the commodity in this country particularly, for here the per capita consumption of pure coffee is larger than in any other country on the globe. When prices are high we cannot do as dealers did in Europe—reduce the price by reducing the quality—by the mixture of chicory, rye, date stones, and burnt figs—because the American consumer insists, and justly too, in buying his coffee in the bean.

"For this reason if for no other coffee culture cannot fail to pay large dividends on investments. Yet in addition to these there are the questions of comparatively small outlay and cheap labour. The latter has been the great difficulty up to the present time, but is now overcome by the use of improved machinery and other labour-saving appliances. The decreased supplies from Java, Ceylon, and other countries in the East Indies owing to what is claimed to be the worm disease rot and other causes of a like nature, but which is in reality due to an overworked and worn out soil make the time ripe and favourable for a new departure in coffee culture in this country.

"It is a fact not generally known to Americans that on their own continent, nay at their very doors, there exists the agricultural capacity and climatic conditions for the production of all the coffee that is required for consumption in the United States, and in addition, to supply Europe eventually. Along the entire length of the Andean Range, coming up from Peru in the south and extending north through Central America into Mexico, and including the West India Islands, there is every facility and opportunity for the successful and profitable cultivation of coffee, rivalling, if not actually excelling in quality, the much vaunted products of Java and other countries in the eastern hemisphere.

"The topographic and climatic condition of Mexico and Central America are especially adapted for the production of varieties as choice in bean and as rich in flavour as the finest products of Java, and so excel untold tenths of that grown in the latter country, which, were it not for the fact of being grown on that Island, would not deserve to be ranked with the average products of the former countries. While the most favourable coffee producing district in Mexico are to be found on the arable lands of the Andean Range, excellent coffee may also be grown on the plains of the interior as far north as Sinaloa as well as on the Gulf coast from Yucatan to Tamaulipas. The great mass of Mexican territory consist of an elevated plateau formed by an expansion of Choterdilleras, from which terraced slopes descend with a more or less rapid inclination toward the Atlantic on the east, and the Pacific on the west. This vast tract composes one of the richest and most varied zones of the world for while its geographical position secures to it tropical vegetation, the rapid differences of elevation which characterise it, afford it the advantages of a temperate climate, thus combining within

its limits an almost unparalleled exuberance and multiplicity of natural products.

"The differences in climate depending on the degrees of altitude are so great that the products including coffee comprise all that are to be found between the equator and the polar circle. Its adaptability to the production of fine coffee has been thoroughly tested by more than fifty years of experience in its cultivation, which experience has fully and satisfactorily demonstrated that in profit to the planter as well as in the superiority of its product, Mexico has no rival among the coffee producing countries of the world. The area adjustable to its profitable cultivation is almost illimitable as far as natural capacity is concerned, being only limited by the extent of land brought under cultivation. The cost of labour is also cheap, never exceeding 25 cents per day.

"The finest coffee in the world comes now from Guatemala, bordering on the little known, and until recently almost totally neglected States of Chiapas and Tabasco, in Southern Mexico. Excellent coffee is now grown, but in limited quantities in the former, and coffee of very fair quality in the latter this too without the aid of intelligent cultivation or modern appliances for hulling or properly the bean for market. On the district of Toepic is grown a coffee rivalling, if not actually exceeding, the far-famed Mocha and Cordoba produces a coffee superior in size, style, colour, body and flavour to many of the much vaunted Java growths. The product of Oaxaca excels that of Jamaica and Ceylon, while the product of Michoacan equals the finest of the Maracaibo varieties, or the best of the East India coffee so much prized in English markets.

"That Mexico has not heretofore assumed first place in point of production and exportation of coffee and that rank to which its merit entitles, it is due to other causes than to unadaptability of the soil and climate, limited capacity of area, quality, or profit to planters. It is attributable alone to those that have so long retarded all the other agricultural and commercial developments, among which may be mentioned the civil disorders, lack of knowledge in intelligent cultivation, modern methods in curing, and scarcity of capital to prosecute the industry in a successful and profitable manner.

"Under the stable and practical government of Diaz and his Cabinet, the Republic of Mexico had become one of the greatest and most progressive countries in our continent. The era of revolution appears to have passed away for ever the pronunciamiento exists there no longer? railroads, telegraphs, telephones, the electric light, newspapers, and schools are rapidly superseding them, the eyes of the home seekers of the world are turning towards the rich possibilities of a country so long dormant and awaiting development. In a very few years from now, the rich and fertile plains of Mexico will be peopled by a population as energetic and progressive as they who built of and made progressive the erstwhile wild and uncultivated lands of our western country."—*Indian Agriculturist*.

PINEAPPLE-JUICE DIGESTS ALBUMEN.—It is not generally known that the juice of the pineapple contains a proteid-digesting ferment; its action is weak, it is true, for 3 oz. digest on'y 10 to 15 grains of coagulated albumen, but it acts equally well in acid and alkaline media, and best in a neutral fluid. The juice also contains a milk-curdling ferment. When we speak of any enzyme being weak, it does not follow that the dose of it must be proportioned to its strength; for it is probable that a small dose will act as well as a large one, by setting up the process of digestion in a fresh line when the digestive function of the stomach is impaired. Then the peptic secretion follows the lead. On that basis, a slice or two of pineapple at dinner is not a bad thing.—*Chemist and Druggist*.

NOTES ON PRODUCE AND FINANCE.

NOT CREDITABLE TO THE NATIONAL TASTE.—The latest suggestion about the popularity of Indian and Ceylon teas as compared with China is that the palates of consumers are vitiated, and that their present preference reflects on the national taste. This is the opinion of a writer in the *Liverpool Courier*, who says:—"Commercially [there is no necessity to regret the change which has taken place in the course and volume of this important item of merchandise. India and Ceylon are British possessions, and British capital has been invested to an enormous extent in this particular trade. And yet the transformation which has been achieved is not at all creditable to the national taste. Indeed, there is reason to fear that we have ceased to have any just ground for sneering at the French lack of appreciation for tea on the score of their inability to brew it properly or recognise it when it is really good. In the days of the China monopoly there also existed a high duty. An impost of 2s per pound might be very unjust, but at all events it rendered the importation of rubbish a business not worth embarking upon. We do not say that if the high duty were to be re-imposed the old conditions of the trade would be restored. Far from it. Primitive habits in an isolated way may live far into modern civilisation, but when once they have been eradicated it is, whether for weal or woe, for ever. But why has China tea fallen into the third place? First of all, because it continues dear. It is still prepared by the old manual processes, while Indian and Ceylon teas are dealt with by machinery, which, for anything that we know, may be capable of making tea out of almost anything. Even new laid eggs can now be fairly well counterfeited by machinery. Secondly, China tea is mild in flavour, and the doubled consumption in Great Britain has brought with it a great deterioration of taste. A 'strong syrupy tea' is what the advertiser announces, and apparently this notion of the plant has become popular. It is not realised that strength means tannin, and that tannin is another term for indigestion. Thirdly, while Ceylon and Indian teas are much cheaper to the consumer, as that individual mistakenly supposes, they pay the retail dealer much better than China teas, and therefore the latter misses the opportunity of extolling them while disparaging the virtues of the more delicate beverage."

SUCH GOOD OLD DAYS.—Presuming that the writer is not personally interested in the China tea trade, but is really lamenting the good old days when he could satisfy his desire for Chinese tea without the "strong twang" he so much dislikes, his picture of the "once upon a time" is quite touching. "Good strong full-bodied tea at eighteenpence per pound," he says. "That is the brand in vogue today! Once upon a time one could have gone to the house of a friend with the certainty of receiving an enjoyable cup of tea, whether one liked it with milk or sugar, or without one or both of these additions. Now the almost universal assumption seems to be that the visitor likes a strong 'twang' to the cup which ought to cheer without inebriating. We can easily imagine that those who tell us we should take our tea without either cream or sugar may be right, and that it would be no great punishment to the sweet-toothed to drink what used to be three-shillings China tea prior to the last reduction by the Chancellor of the Exchequer under such conditions, if properly infused. But what amount of sugar and milk can sufficiently modify the character of the coarse, pungent liquid as a rule now purveyed as tea?" The transfer of patronage from China to Indian and Ceylon teas is commercially all right. We are far from saying that the two latter may not be discriminatingly used without any material injury to the consumers. But the fact remains that the change in taste has been artificially brought about. The consumer likes to have what seems the choicest tea, and it pays the retailer to encourage the natural tendency. This is why so many people now regard China teas as once costly and insipid. In point of fact, it is to those

who know how to prepare it absolutely economical, and it provides a delicious delicacy otherwise unobtainable. It is the custom of the age to sneer at epicures, even though all classes in their various spheres profess in some degree to belong to the order. But perhaps the most regrettable circumstance connected with the revolution in the tea trade is the fact that it is so difficult even for people who are willing to pay for China tea to get it pure. They have, as a rule, to be content and feel thankful when they can obtain a moderately decent blend. It is sad to think of the writer, with epicurean taste and stoical philosophy, yearning for pure China tea, willing to pay for it, yet only able to obtain a moderately decent blend, and withal generously admitting that, in spite of this, it is "commercially all right." But he should kindly remember that it is all a matter of taste, and that his views as to the delicacy of the Chinese teas he so fondly admires may be due to some natural deficiency in his power to appreciate the more robust, but nevertheless admirable, teas grown in India and Ceylon.

THE CROP OUTLOOK.—Discussing the position of Indian tea, the *Grocers' Chronicle* says:—"It is now pretty well known in the market that there is only about as much of the crop unsold as there was at same date last year; and, as the 12,000,000 lb. surplus is all disposed of already, and prices have had all the fall they are likely to have, a more confident feeling prevails, and importers are taking heart of grace to refuse bids which a month ago they would have been willing to accept. The only disturbing element in the forecast of events is: What will Ceylon do during May and June? It will be remembered that at the moment when Indian tea was up to 10d. last April, heavy supplies of Ceylon, owing to a heavy rainfall, were unexpectedly sent forward, and smashed the market here down to 8d. inside a week or two. This year, however, prices are 40 per cent lower. Ceylons themselves have never been previously so low, and it is no secret that the agents of several leading gardens have cabled out instructions to pluck fine, so that it is improbable that supplies will be much in excess of last year even allowing for the natural expansion of the industry and the bringing into full bearing of young gardens which last year sent nothing to market. The season is now closed at Calcutta, and it is expected that the crop will weigh out 111 millions or thereabouts in London."

LAST WEEK'S TEA MARKET.—Of last week's market the *Grocer* says:—"There having been a considerable lightening of supplies in importers' hands, and the parcels now offering not being pressed forward so eagerly as they were a short time back, the market for Indian tea has acquired much more stability than of late, and the nucleus of about 23,000 packages this week have been characterised by greater buoyancy than before at again stiffer rates. This remark, however, applies more directly to fine and finest grades, strong in cup, and with other points of excellence—such as being last of the season and of autumn flavour—which teas, being briskly competed for when they are comparatively few left, have fetched another advance of quite 1d to 2d per lb.; and this helps to prove that the trade in the article is in a sounder and healthier condition than has been generally supposed. Medium and useful qualities have likewise gone off more favourably for holders, though not, of course, to the same extent, whilst the broken kinds, with fannings and very low sorts, have been taken slowly at only a trifling, if any, improvement in value. More animation was noticed at the sales of Ceylon, and the market has a better tone. Useful medium and fine teas sold very well, and values for some of these marked an upward tendency. The absence of finest grades has its effect on prices, and no rise can be looked for until there are fewer common kinds offering. Low rates are still recorded for the latter."

WHAT IS A BROKER?—The *Produce Markets' Review*, taking its cue from the correspondence on the subject in the *Public Ledger*, has been discussing the question, "What is a Broker?" It says:—"A very remarkable and serious change has taken place among City

brokers of late years, and a considerable proportion of them appear nowadays to consider themselves no longer bound to act within the old and settled lines of trade. It is the commonest thing in the world for a broker to act in one or all of the capacities of importer, merchant, wharfinger, dealer, or exporter, obtaining a profit in each capacity, though signing contracts as a broker, and charging a commission which is supposed to disclose the whole amount of his profits. In addition to this, there is, of course, a large pawbroking department in almost all leading brokers' offices, but this may be regarded as quite a legitimate development of their business as they make an open charge for their services in this line. It is here, in fact, that the division line may be found. There is no objection whatever to a man, who generally calls himself a broker, and acts as such, obtaining any profit he sees fit, so long as he discloses the fact, at the time of the sale or purchase, that he is buying or selling on his own account, and that in addition to his commission he is making a gain which he does not desire to disclose. To such a course there can be no moral or legal objection; but it is very different when an intermediate profit is obtained without such disclosure. The question would certainly, even in such a case, still remain whether it is desirable for a person who is purporting to act for A or B, or for both of them, to be in the position of a professional man accepting a fee for disinterested advice, when he was really all the time looking after number one, and acting in his own interest. But if A and B chose to agree to his doing so, it could only be their judgment that could be questioned, and not the propriety of the action of the broker."

BROKERS WHO DEAL ARE NOT DISINTERESTED.—"It is nowadays a very ordinary occurrence to hear the so-called brokers in the produce markets state that it is impossible for them to live by their brokerage, that prices are so low that they could not exist on half or one per cent., while expenses are increasing; so that the only method by which they can keep their heads above water is to obtain a profit beyond their brokerage. This state of things cannot be too widely known especially among buyers in the country, who imagine that by going to people who call themselves brokers, they can get at the fountain-head, pass by intermediate profits and buy as cheaply as the dealers who have hitherto supplied them. To those acquainted with the working of the produce markets, such a delusion would be so ludicrous that it could never occur. This is only one aspect of the matter, because the question arises of how the interest of the importers of commodities can be promoted by such a state of things. If a broker is buying on his own account, he cannot be a disinterested adviser as to markets. Consciously or unconsciously, his advice to the importer must be governed by the state of his own stock, and by the opportunities he sees of making a profit for himself, beyond what he discloses. From the importer's point of view, it is sufficiently undesirable that a commission could be jointly paid by the buyer as well as by the seller, but this sinks into insignificance by the side of the fact that the nominal broker is, in many cases, the actual purchaser on his own account."

THE SILVER QUESTION.—It is the special plea of the bi-metalists, says the *Financial News*, that their theories, carried out in practice, would produce stability between silver and gold. It is not our intention to discuss the advantages or demerits of a double standard today; but it is worth pointing out that the relative value today of an ounce of gold and an ounce of silver is, roughly, as 23 to 1, which is slightly different from the formerly-accepted ratio of 16 to 1. It is, however, of the highest importance that some approach to stability should be maintained between the two metals, and we understand that a committee has been formed with the special object of impressing upon Mr. Goschen the necessity of trying to create some stability between the two currencies of the Empire. What can be done to permanently

remedy the difficulty is a problem which has long troubled the wisest heads; but until some solution be found there will be an unavoidable element of speculation in the ordinary business of banks with Indian connections, which is as undesirable for the public as it is for the banks themselves. If the manager in London carry on his business on ordinary lines he must sustain a loss by a continued fall in the rupee. On the other hand, it might be thought that the loss in London must be to the profit of the Eastern branches; but, unfortunately, experience proves that this is not by any means always the case. As a result, nearly every Indian bank manager finds himself compelled in self-defence to "take a view," and the bank has, against its will, to speculate in order to try and avoid the speculative risks of constantly fluctuating exchange. A considerable fall has taken place lately in the shares of some of the Indian banks, presumably on the ground that they must lose heavily by the fall in the rupee, which yesterday was only 1s 2 15-16th d. Apart from the special circumstances of the Hong Kong and Shanghai Bank, it does not follow that any part of the capital of any of them is permanently gone. No doubt if their resources had to be brought over from India to this country tomorrow, there would be a serious loss; but the deposits of these banks are nearly all for fixed terms, and much is retained in London to discount Eastern trade bills and practically never leaves this country.—*H. and C. Mail*, April 1st.

SERMO SINENSIS.

(Communicated.)

"Well, Awai, what's the news and how are prospects?" I enquired, as I took a proffered seat in the great teaman's sanctum.

"Allow that tea news b'long welly had, London market b'long welly culio, that Mining Lane man have got that *inferlenza*, Leo-sha * man no got lico (rather a bold statement, I thought), and Melican man welly sick along that silver pidgin. Plospix! no got plospix."

In such not very encouraging manner did the Napoleon of the tea trade commence what subsequently proved to be a rather interesting statement of his views, or so much as he cared to disclose of them, upon the present position and prospects of a trade with which his name has been identified for the past thirty years, and of which he personally has been the burning and shining light for the last quarter of a century.

Here a preliminary crocodile appeared to have the double effect of clearing his throat and of freeing his ingenuous thoughts of that pidgin English dress with which he usually delights to clothe them, and he delivered himself of his views of the situation much as follows:—

"There is no doubt about it that the China tea trade is in a bad, nay in a very critical position. It is fashionable at the present moment—but fashions happily change or they wouldn't be fashions—to place nothing but Injun and Saylong teas before the London public. To derry China tea, in fact to cry stinking fish, is the silly inspiration of the moment. And those most guilty of this defamatory practice are the very ones who have fattened and batted upon the profits of China tea, for many a long year past.

"Perhaps there never was a time in the history of the trade when the public got such good value in China teas for their money as they are getting today, clean, pure, innocuous, and yet they prefer the coarse, strong, astringent stuff which India and Ceylon turn out by the ship-load. Well, if this isn't fashion, and a welly culio, fashion, too, I should like to know what it is."

"But you don't think the British public will take to China tea again, do you?" I asked.

"Can see, can savey. This year will present one of the last chances of reviving our trade. If we send

* Chinese form of "Looshia," of course.—*Ed. T. A.*

but small supplies to London our fate is sealed. What is wanted is a large crop, not necessarily of very high quality, at low cost. The attempt must be made to undersell our rivals, and so re-establish ourselves in public favour. The weather all along favours the idea of a crop certainly not smaller than that of last year, and exchange and freights will contribute to lay it down at an unprecedentedly low cost. Personally I don't wish to see high prices at Hankow, and I hope foreign buyers won't pay them."

"You said just now that China could undersell India and Ceylon. Is that a fact?" I enquired.

"Certainly. I hear that the average cost of the Indian crop is 8d. per lb., and of the Ceylon 8½d. The average price paid last year in China was Tls. 16, Shanghai 15c, or thereabouts, and that at 4s 2d exchange and a possible 25c per ton freight would make the lay down cost 7d per lb."

"Do you think that there is any probability of a reduction of the inland burdens China tea is called upon to bear?"

"I hope so, but I don't think so. The mandarins appear obdurate (*very strong stomach* were the exact words) Wo native teamen want to see the taxation lightened just as much as foreigners do, but the Tsungli Yamèn does not hold the guild in very high esteem, nor does it appear to have had much regard for the elaborate reports on the question drawn up by the foreign Chevezes some two years ago. At the risk of being tedious let me once again show you how China tea is handicapped. The first charge on the "made leaf" is Tls. 1.25 per picul, the shreffago in fact, exacted by the various local authorities. Then another Tls. 1.25 per picul is the well-known likin tax, levied to defray the cost of protecting the article in transport; and finally there is the Customs' export duty of Tls. 2.50 per picul. These make a sum of five Haikuan taels a picul, or 23 per lb. So a clean, sweet, strong Keemun at Shanghai Tls. 18 per picul, relieved of these burdens could be laid down in London at 6½d per lb, and a Tls. 10 Shantam at 2½ per lb. And if that wouldn't knock the stuffing out of Fujun and Saylong, I don't know what would."

After this little flight of fancy on Napoleon's part, I asked him what sort of preparation was being made for the coming season.

"Well," he said, opening his press copy letter book, "this is the substance of what I have written to the sixty teamen with whom I usually do business. You must be prepared for very much lower prices than you got last year, and a slower market to commence with. If you don't fire your teas with pro. per charcoal, tar will develop, and you must look out for squalls. Tls. 60 per picul, which after all is only 2s 1½d per lb., will doubtless be paid for a few crazy chops, and then begins the sheer descent. And these are my ideas of safety. I give you last year's price paid and the laying down cost in Hankow that you should not exceed this season."

"And do you think that your correspondents will confine themselves to your limits?"

"Well, they certainly ought to be able to hny the leaf in the country to give them a very good profit at my limits. If they exceed them, and grief crises, they will have only themselves to blame."

"As regards the size of the crop, what are your views?"

"Truly, I don't think that on the whole it will turn out to be any smaller than last year's, and I hope it will be as big, to prevent our being 'crowded out' by Indian shipments. There will be a falling-off in the supply of Kiukiang teas, as only 250 hongts are opened in the Kiargai districts as against 358 hongts last year, and the falling-off will be chiefly visible in the medium Ningchow kinds, which lost money heavily for both producer and shipper. The number of hongts in the Hankow district shows an increase, but supplies will not much exceed last year's. I look for a very large business in all teas costing from Tls. 7 to Tls. 17. These, then, briefly are my views; a couple of months will show how far I have been off the mark. Just tell me two things before you go: what like are the Russian orders, and how much China tea will London take this year?"

"I could well wish," I rejoined, "that you had asked me something easier. However, it is generally held that Russian orders will be for 30 per cent. less tea at 30 per cent. less cost."

"Yes," he replied, "but telegrams can alter those conditions." And I was compelled to admit the possibility.

"As regard consumption," I added, "you had better keep your eye on the London Board of Trade figures. If you look them up you will find that the year's deliveries were 233,000,000 lb., made up of

Indian tea.....	101,000,000
Ceylon.....	54,000,000
Java.....	4,000,000
China.....	74,000,000—233,000,000

but as the Indian export is estimated at 120,000,000 and Ceylon 80,000,000 lb. for 1892, unless home consumption increases it will be a bad look-out for China unless she can do the thing on the cheap. But tell me one thing more. Did the teamen lose much last year?"

"Why, of course they did, all along the line. I lost Tls. 85,000, and am not afraid to own up to it."

This sum appeared to me rather a staggerer, and I dare say that he observed a look of incredulity on my face, for he soon observed: "Some flens had a little spare inside that less"—a fact I never doubted, for it must have been a cold day, indeed, when "our good old friend Awei" got left, I thought.

Opening a pint of the celebrated "Shun Fat" white seal, he invited me to drink to better times, and "large o'hance" this season, and the genial operation having been duly performed, he obsequiously bowed me out with "a smile that was child-like and bland."—*N. C. Herald*, March 25th.

THE CHINA TEA TRADE.

To the Editor of the NORTH-CHINA DAILY NEWS.

Sir,—It is consoling to find from the "Sermo Sinensis" in your yesterday's issue that the Napoleon of the tea trade is still vigorous. His plan of campaign is certainly a bold one; viz., to send to London big supplies at low cost, to fight and undersell our rivals and thus re-establish ourselves in public favour. He is, however, too sanguine in my opinion in thinking that China tea, taxed as it is, can ever undersell India and Ceylon, and he is certainly quite wrong in his figures as to the average price paid

* Ceylon costing 8½d per lb., against 8d for India is rather a different idea to Ceylon costing only 6d. But we have seen that calculation made.—*Ed. T. A.*

in North-China last year; which was about Sh. Tls. 29 per picul, instead of—as he puts it—Sh. Tls. 16. The cost to the toamen moreover must have been considerably more than Tls. 29, as they are supposed to have lost heavily. As to the low exchange, etc., this of course benefits our rivals equally with ourselves.—I am, etc.,

CHAA-SZE,

23rd March.

To the Editor of the NORTH-CHINA DAILY NEWS.

Sir,—It was with great pleasure I read the article communitiated to you under the heading of "Sermo Sinensis." If the "Sermo Sinensis" has done no other good, it has at least led people to talk over what will soon be the "business of the hour." I think it would be a great pity to let the matter drop now, and some good may perhaps be expected from the great teaman's co-operation. The statistics in your correspondent's article were only too correct, and it is an indisputable fact that, if the China export falls off this season, China as a tea producing country is irrevocably doomed. I noticed that your correspondent estimates the Ceylon export next year at 80,000,000 lb. I believe it will be nearer 100,000,000 lb., and if so, it makes the position so much the worse. The China tea trade has now come to a critical period and instead of as in former years meeting with no competition, it has now to contend against British colonies with no taxation and is therefore handicapped. That internal levies are likely to be established I quite agree with the "Napoleon of the tea trade" is most improbable, but that export duty must be done away with, there is no doubt, or otherwise the China tea trade is finished.—I am etc.,

23rd March.

TEA MERCHANT.

To the Editor of the NORTH-CHINA DAILY NEWS.

Sir,—The opinion of the "Napoleon of the tea trade" in China is doubtless of inestimable value to would-be tea-buyers in forecasting the "prospects" of the coming season, but a more important factor upon which to base one's action is the opinion of the dealers at home.

This, as far as my information goes, is unanimous that the British public does not want China tea at any price, an opinion, at first sight, hardly consonant with the fact that seventy million pounds of China tea were delivered in London last year, which, deducting the export of twenty-five million pounds, gives an actual home consumption of forty-five million pounds or nearly one quarter of the total of the tea actually drunk in Great Britain and Ireland. In the year of grace 1891, the total consumption, of all kinds, was 200,000,000 lb. The home consumption of China tea in the preceding year, 1890, was fifty-five million pounds out of a total of 194,000,000 lb. or in percentages:—In 1891, 22½ per cent of the consumption was China tea; in 1890, 29 per cent; and in 1889, 31 per cent.

Thus roughly speaking, one-fourth of the tea drunk in England is still China tea, and this appears to have been taken mainly on account of its cheapness for the purpose of "blending." Messrs. Shopard & Co., the well-known Mincing Lane brokers, write in their Annual Tea Circular, published in January of this year:—"As regards good common to medium Blacks received the last few months, though laid in on apparently favourable terms, the heavy supply and very low level of prices current for good common to fair Indian and Ceylon Teas, especially the latter, have weighed down the value of anything in China Congous selling over Gs. per lb." Messrs. Shopard further state "There has been a more general and widespread effort on the part of dealers throughout the country to revive an interest in *fine China Congou*, which is being pressed on the notice of consumers at and under 2s. per lb."

In the face of such low prices and of such unprecedented efforts the only result we see is a steadily dwindling consumption. With an anticipated production this year in India and Ceylon of 200,000,000 lb. Mr. Awa's anticipation of "a very large business in all tea coming from Tls. 7 to Tls. 17" if realized, will, I hold, only result in forcing down prices still lower in London.

Happily for the native tea-man, the only one other large black-tea consuming country, Russia, still sticks to the Celestial leaf and, as long as that market remains as it is, the Chinese may continue to pack tea for Russian consumption under existing conditions, but as long as their trade is handicapped with differential imposts in favor of India of twenty-five per cent. (and, given the preference of the "masses" at home for strength with coarseness as against delicacy with weakness), no efforts of producers and shippers can succeed in placing China tea on the London market in any quantity with the hope of a profitable result.

The moral of which is that, as long as the Export Duty remains in force, the China tea trade with England is doomed, and hence producers and shippers should perseveringly devote all their efforts to the removal of this burthen. To pursue their trade under its weight is but to go on from year to year "flogging a dead horse" until nothing of the carcass is left.—I am, etc.

THE COST OF CEYLON TEA.

To the Editor of the NORTH-CHINA DAILY NEWS.

Sir,—With reference to the correspondence appearing in this morning's issue of your paper on the subject of the China Tea Trade, may I be permitted to make a few remarks, with a view to comparison, touching the cost of production of tea in Ceylon, having recently visited the Island, where I had an opportunity of gaining an insight into the working of a tea estate. Assuming, as stated by "Chaa-sze", the average price paid per picul in North China last year to have been Shanghai Tls. 29, and the cost to the toamen Tls. 30 as they are stated to have lost, the cost per lb. to the teaman would be about 22½ cents* or 10½d. sterling with exchange at 4s., this being the actual cost of bringing the finished article into the Market.

Taking this into consideration the following figures may be of interest to your readers as furnishing some idea of the necessary expenses incurred by a tea planter in Ceylon, in order to enable him to place his tea on the London market.

Cultivation	5	cts. † per lb. of made tea.
Plucking	5	" " "
Manufacture including fuel, tea makers' pay, cost of packages tea lead, etc.	6½	" " "
Salaries and contingencies	7½	" " "
Repairs to Factory	3	" " "
Transport to Colombo	1½	" " "
Freight and selling charges	10	" " "
Total	36	cents at Ex. 1s 4d = 5½d.

The cost of plucking varies, according to whether the planter wishes to pluck fine or coarse; if the latter, which means plucking five or more leaves instead of three or four, the coolies are enabled to bring in a very much larger quantity of leaf at the end of the day's work. The manufacture being done entirely by machinery, the cost, whatever the quantity of leaf to be manufactured, remains the same, and as roughly speaking 4 lb. of green leaf = 1 lb. of made tea, it follows that the larger the quantity of green leaf, the less is the cost per lb. of made tea.

* Of a dollar.—Ed. T. A.

† Of a rupee.—Ed. T. A.

‡ Ordinary plucking is confined to the bud plus two leaves.—Ed. T. A.

On the subject of fine and coarse plucking, there is a considerable amount of controversy in the island, owing to the fact that although plucking coarse enables a planter to turn out large quantities of manufacture of tea, the quality is inferior, the coarse leaves being broken in the rolling process and mixing with the finer grades when being sifted, thus detracting from the appearance of the dry leaf and causing a deterioration of the liquor. The argument in favour of coarse plucking is to the effect that, in addition to the initial cost being less, quantity realising less per lb. is more remunerative than a less quantity of a superior quality, and it is owing to this view of the case being mostly in favour, that such large quantities of common teas have been shipped to London during the past year. Planters are alive to the fact that shipping these common teas is injurious to the reputation of the island, and in all probability this view, coupled with the strong demand for fine Ceylon teas and the high prices being obtained for these, will prevail in the end.—I am, etc.

TAVELLI.

—N. C. Herald, March 25th.

“FISHING FOR PEARLS IN AUSTRALIA.”

The article so headed in the *Century Magazine* ought to have been entitled, “Fishing for Mother-of-Pearl Shells.” The writer, Mr. Hubert Phelps Whittemarch, an American, speaks of those large shells as if they were the exclusive source of the pearls of commerce and adornment; although he states that ten tons of them are sometimes opened without the finding of a single pearl. In the case of the true pearl oyster it is rarely the case that 100, weighing about 10 lb., are opened without some pearls, “seed pearls” at least, being found. Had Mr. Whittemarch added a study of the literature of the subject to his practical experience, he would have known that the large shells, *Avicula (melanagrina) margaritifera*, are sought for and valued primarily on account of the masses of mother-of-pearl they yield and only secondarily for the sake of the pearls occasionally found in them. On the other hand the true pearl oyster (really a mussel), *Avicula (melanagrina) fucata*, is, from its small size of little or no value for mother-of-pearl purposes, but is immensely superior as a pearl yielder. Banks of this mollusk exist off the coast of Western Australia, as well as in Ceylon, the Persian Gulf and other places, the Ceylon banks being probably the most productive. The interest of the paper in the *Century Magazine* is not scientific but practical, being written by a man who not only took part in “pearling” as the pursuit is called, but actually dived (in a diving dress) in search of the precious shells, when he lost the services of the man he had employed from the prevalent curse of drunkenness. Experience in these Australian fisheries confirms the conclusions arrived at by those who have watched the fisheries on the north west coast of Ceylon, that beyond a depth of ten fathoms it is not safe for an ordinary, unprotected diver to go. Seven fathoms is the average on the Ceylon banks. At greater depths there is not only danger from the pressure of the superincumbent water but from the coldness of the temperature. For greater depths than ten fathoms, therefore, the Malay divers are roolaced in Australia by Europeans protected by the diving apparatus of india-rubber dress, metal helmet, glass face piece, pipes, air pumps, &c. The hazards which such divers run are vividly described. The illustrations given with the article include:—a picture of the shells of the oyster; native divers (with neither string, stone, nor basket); examining the oatch; diver and turtle; diver and shark; diver (in diving dress) at a depth

of 100 feet; finding the bottle (with an advertisement on it); after a squall; and necklace of diamonds and American pearls. The obviousness of this latter illustration to Australian “pearling” is not so apparent as the beauty of the ornament. Omitting profatory matter on the general history of pearls, and the erroneous statement that the true pearls of fashion are yielded only by the so-called pearl-oyster, or mother-of-pearl shell,—the mother-of-pearl shell not being the true pearl oyster,—we proceed to extract as follows:—

Around the northern and western coasts of Australia the mother-of-pearl shell has been found in great quantities, and it was on these coasts, which are still unexplored, and inhabited only by natives, that the writer gained what knowledge he possesses of pearl-diving as it is followed today.

Formerly it was carried on in two ways, by native divers and by dress-divers. A few years ago the aborigines were easily induced to sign a contract binding them to their employer for the diving season, and in remuneration for their labour received the usual pay—food, tobacco, clothing from the neck to the knees, and a blanket. They lived aboard a schooner on the fishing-grounds during the five summer months, diving from small boats without the aid of sinker or other appendage, and in water from twenty to sixty feet deep. Each boat was in charge of a white man, who sculled the boat along and kept his “boys” up to the mark. Excepting an hour for dinner, they remained away from the schooner from sunrise to sunset. A good native diver, if shells were moderately plentiful, would get from sixty to one hundred pairs per day.

A curious feature among the native divers is that toward the end of the season their long, curly, jet-black hair becomes a straw color, presumably through the action of the salt water and the sun, and forms a ludicrous contrast to their intensely black faces and bodies. Since bleaching the hair has become a “fad” among civilized nations, perhaps the above recipe may prove useful to some of my readers.

Native divers are not in much request at this time, owing to the shell being pretty well worked out in shallow waters, and it has been found by long practical experience that naked native divers cannot work with any degree of success beyond a depth of ten fathoms. For this reason it will be readily understood that, as the greater part of the shells now found have to be searched for at a depth of water exceeding ten fathoms, they can be obtained only by means of the well-known diving-dress.

During three years spent on the coast of Western Australia I never knew an instance where an aborigine had been broken in to work in a diving-dress, their objection to it arising from some superstition. The greatest depth at which pearl-shells were found in payable quantities when I left, in 1888, was eighteen fathoms, and the main portion of the diving is now done by white men and a few Mongolians.

Dress-diving is by far the most approved method, as the diver can remain under water an hour or two if he chooses, can dive much deeper than the natives, and is able to work all the year round.

The difference between the mother-of-pearl shells and the true oyster shells becomes pronounced when we are told that a pair of the former weigh about two pounds, while it is certain that a pair of the latter (shells only in both cases) must be under two ounces. The former sell for £10 to £150 per ton, while the latter are left in thousands of millions on the beach opposite the Ceylon banks, with no demand for them even as sources of lime. To quote again:—

One of the most essential adjuncts to a dress-diver's outfit is a good “tender.” It is he who manages the boat, holds the life-line, and looks after the general safety of the diver when below. A tender must keep his weather-eye open for squalls and collisions, must attend to signals, and must not get his man mixed up with a diver from another boat. He should so hold the line that he just

feels the movements of the worker below, never so tight as to retard free action, and never so slack as to drag on the bottom and probably get foul round a coral-cup's base, and so condemn the diver to a watery grave. Indeed, he should be a wide-awake fellow, quick to act in an emergency and constantly alert.

The mode of working is as follows: A "patch" of shell having been discovered, the boats beat up to the windward edge, and then drift down over it with a fouled anchor; that is, with the anchor upside down, so that it does not catch, but allows the boat to drag slowly over the ground, the speed of drifting being regulated by paying out more or less chain. When the diver finds that he is off the patch he comes up, the boat takes to windward again, and drifts over it as before. A patch being often one or two square miles in area, it is next to impossible to go over the same ground twice, though the entire fleet of 150 boats often work on the same patch.

The author's personal experience as a diver is thus given:—

Once again we were ready to start, all except Joe, who, knowing I could do nothing without him, wanted a few more days to finish his spree. I coaxed and entreated, but to no purpose; expenses were going on, and nothing coming in, and, after two days of impatience and chafing under my own helplessness, I made up my mind to try to dive myself, and the next tide I left the creek with that intent. The following day I made my first descent, and it is impressed very vividly on my memory.

Long before old Sol had made his appearance above the horizon that morning I crept up on deck to take a survey of my surroundings. The first streaks of dawn were lighting up the eastern sky, and in the distance I could see the dim outline of the "ninety mile" beach, ninety miles without a hill or tree, creek or habitation—nothing but white, glistening sand. Beneath, the "mighty liquid metronome" lay calm and peaceful, ruffled as yet by the morning breeze, and all around were anchored the pearlers. At sunrise I called the boys, told them of my plans, and chose one named Ketchee for my tender. After partaking of our morning coffee I proceeded, with Ketchee's help, to don the ponderous diving dress. The rubber suit, all in one piece, and which one gets into through the neck, was the first article to put on; then the leaden-soled boots and the corselet, to which the helmet is screwed, and the chest- and back-weights—in all weighing some fifty or sixty pounds. I stepped on the ladder hanging over the boat's side, and had the life line, air pipe, and helmet attached; then the order to pump was given, and, last of all, the face-glass was screwed up. Oh! that there had been a wrench with which to screw up my courage as well. It had sunk to the bottom of those leaden-soled boots, and though Ketchee tapped the helmet, intimating that all was ready, I felt loath to let go. Thoughts of sharks, octopi, and other monsters of the deep flow through my brain, and I felt sure that the pipe would burst, or the boys stop pumping, or some unforeseen accident would occur.

As I hesitated, thinking of some excuse to have that face-glass taken off again, I glanced up at Ketchee, still undecided what to do, and saw him grinning all over his yellow face at my discomfiture. That decided me; I could not stand being laughed at by a Malay; so without more ado I grasped the guiding-line firmly, and dropped.

Splash! The water closed over me with a buzzing sound, and the air whistled in at the top of the helmet with a weird noise, and I saw the bottom of the boat just above me. My ears began to ache, and the pain increased as I slid down and down, until I fairly yelled with the agony caused by the unusual pressure of air on the ear-drums. Still swiftly down I went—would the bottom never touch my kicking feet? At last I reached it with a thud, and instantly all pain ceased, and I scrambled to my feet, full of curiosity.

My first thought was, how foolish I had been to dread leaving the monotonous sea and sky above, when, only ten fathoms below, lay an overhanging scene of

beauty—a paradise, although a watery one. The ground I stood upon was rock of coral structure, grown over with coral-cups from minute size to four and five feet in diameter. Sponges as high as one's head, sponge-cups, graceful corallines, and sea-flowers of new and beautiful forms, and tinted with all the hues of the rainbow, waved gently to and fro; while, like butterflies, flitting and chasing one another in and out among them all, were hundreds of tiny fishes, so gay with colors that the historical coat of Joseph would have paled beside them.

Truly it was an enchanting scene, so bright, so beautiful, and so novel withal, that I walked about with curious delight, forgetful of all the means which enabled me to intrude upon the fishes' dominion until I was brought to my senses by a sharp jerk on the life-line. This being an interrogation from Ketchee as to whether I was all right, I answered it in a similar way, and, as I did so, a familiar object caught my eye in the shape of an empty beer-bottle. It stood upright on a little ledge of rock, and I could read its flaming yellow label of world-wide reputation. "Ye Gods!" I cried, "what vulgarity! An advertisement even here! Is there no place on the earth or under the waters where one can escape the odious advertiser?" And then for the first time I began to realize my position: my head was aching, and I was heaving in quick, short gasps; I was oppressed, and an uncanny, eerie feeling crept over me as I tried to pierce the dim azure of the distance beyond, where the shadowy sea-fans moved so languidly, and my imagination conjured up huge forms in the distance.

I was getting nervous, and had therefore been down long enough; so I gave the signal to pull up, and in a few moments was greedily drinking in the pure, fresh air of heaven through the open face-glass. My nose and ears were bleeding profusely, and I spat a good deal of blood also, but as I had been told that this would happen the first time, I was not alarmed. The pressure had opened a communication between the mouth and the ears, and I could now perform the extraordinary feat of blowing a mouthful of smoke through my ears, which all divers can do. After this I experienced no pain whatever when descending, and soon became a fairly good diver.

It was on my third descent that I found the first shell. It contained three pearls which I had set in a ring as a memento, and wore until quite lately, when I discovered that it showed to better advantage on a whiter and more delicate hand than mine, and in the cause of art transferred it thither.

My largest day's work was three hundred and ten pairs of shells; this is rather over a quarter of a ton. The greatest number on record collected in one day is one thousand and five. These were picked up by "Japanese Charley," a little Jap about five feet high, who was always tended by his wife, and whose boat was the prettiest model and the smartest sailer in the fleet. The most valuable pearl discovered on this coast is that known as the "Southern Cross"—a cluster of six pearls in the shape of a crucifix which was exhibited at the Indian and Colonial Exhibition, London, in 1886, and was valued at \$50,000. This pearl was found at low water by an old breach-comber, and was sold by him for £10.

The diver, as the reader may imagine, gets many scares when below. A fifteen-foot shark, magnified by the water, and making a hee-lino for one, is sufficient to make the stoutest heart quake, in spite of the assertion that sharks have never been known to attack a man in dress. Neither is the sight of a large turtle comforting when one does not know exactly what it is, and the coiling of a sea-snake around one's legs, although it has only one's hands to bite at, is, to say the least, unpleasant. A little fish called the stone-fish is one of the enemies of the diver. It seems to make its habitation right under the pearl-shell, as it is only when picking them up that any one has been known to be bitten. I remember well the first time I was bitten by this spiteful member of the finny tribe. I dropped my bag of shells, and hastened to the surface; but in this short space of time my hand and arm had so swollen that it was with difficulty I could get the dress off, being unable to work for three days, and

suffering intense pain thro' the while. Afterward I learned that staying down a couple of hours after a bite will stop any further discomfort, the pressure of water causing much bleeding at the bitten part, and thus expelling the poison.

One of the strange effects that diving has upon those who practice it is the invariable bad temper felt while working at the bottom; and as this irritability passes away as soon as the surface is reached again, it is only reasonable to suppose that it is caused by the unusual pressure of air inside the dress, affecting probably the lungs, and through them the brain. My experience has been that while below one may fly into the most violent passion at the merest trifle; for instance, the life-line hold too tight or too slack, too much air or too little, or some imaginary wrong-doing on the part of the tender or the boys above, will often cause the temper to rise. I have sometimes become so angry in a similar way that I have given the signal to pull up, with the express intention of knocking the loads off the ontire crew; but as the surface was neared, and the weight of air decreased, my feelings have gradually undergone a change for the better, until by the time I reached the ladder, and had the face-glass unscrewed, I had forgotten for what I came up.* It is evident from the number whom I have known to make a first descent, and who afterward positively refused to try again, that all men are not born to be divers. At one time I had for my tender a brawny young Scotchman named Rob, a six-footer, about twenty-three years of age, and as fine a specimen of the genus *Homo* as I ever came across. As was to be expected, Rob had a sweetheart in the "auld countrie," and the one aim and end of his life was to make a fortune wherewith to return and marry the girl of his choice. He had tried the Kimberley gold-fields, and the Silverton silver-fields, without success, and was now anxious to try his luck at diving. I told Rob that I would put him down the first sack day we had to see how he liked it, and when that day arrived, with a few parting injunctions from me as the face-glass was put on, down he went, I acting as his tender. I felt him land on the bottom and begin walking from the boat; he answered the signals all right, and I anticipated no trouble, but before he had been down three minutes he was foul of the anchor-chain, and I had to pull the anchor and Rob up together. By this time he had become thoroughly frightened, and was screaming inside the dress to be pulled up; he had also lost his presence of mind, and had screwed the need-air escape-valve at the side of the helmet the wrong way, thus keeping in the constant supply of air from the pump above, and the dress was in danger of bursting. As soon as we got him alongside I unscrewed the valve, and he was soon on deck, laughing over his mistakes.

About a week after this he made a second attempt, and this time nearly lost his life. As before, he became alarmed, thought that there was too much air in the dress, and tried to let it out by the escape-valve, but screwed it up the wrong way again, shutting in the air; and then, finding the air still increasing in pressure, his presence, of mind again deserted him, and he began to take off the face-glass. Fortunately for Rob, his girl, and my apparatus, he lost consciousness before he quite got it off, and we hauled him to the ladder, kicking and yelling like a madman. He remained delirious for several hours, and when at length he came to his senses, and recovered from his fright, we concluded that diving was not his forte, and that his fortune would have to be made in some other way.

Though pearl-diving, if the fates are propitious, is a lucrative occupation, its dangers are manifold. In the community in which one has to live may be found some of the "toughest" men on earth. A mixture of all nationalities far worse than one meets on a gold-field, and an exciting calling, without restraint or law, are not likely to form a peaceful community. A divor is always at the

tender mercies of his Malay crew, and the slightest accident to his apparatus, such as the breaking of the pump or the air-pipe, ripping the dress, getting entangled on the bottom, or even losing his presence of mind, may end fatally. Then, again, it is most injurious to the health, some dying from the effects after a few months, while deafness and incipient paralysis are common features. But worse than all these are the terrible cyclones that visit the coast, carrying everything before them, and leaving only a track of death and the flotsam and jetsam of wrecked hopes to mark their passage.

CEYLON TEA IN THE ANTIPODES.

Sir Andrew Clark, who praised China tea to his students at the London Hospital and deprecated the use of Indian, is having his opinions prominently brought before the good folks of New Zealand by traders who go in for blends. This is how it is done:—

LECTURE ON TEA TO THE STUDENTS OF THE LONDON HOSPITAL.

Extract from the *Pall Mall Budget*.

"Tea, to be useful, should be first of all black China Tea. The Indian Tea which is being cultivated has become so powerful in its effects upon the nervous system that a cup of it taken early in the morning as many people do, so disorders the nervous system, that those who take it actually get into a state of tea intoxication, and it produces a form of nerve disturbance which is most painful to witness."

Although we are the largest dealers in India and Ceylon Teas in the colonies, we have always strongly advised the public to drink our Blended Teas in preference to Indian or Ceylon alone. We maintain they are too siorly for 90 per cent. of the tea-drinking public; and in England, where such large quantities are shipped, over 80 per cent. are used for blending with China Teas, which are undoubtedly as pure as Indian and Ceylon, and far more refreshing when properly blended. Many inexperienced firms push Indian and Ceylon, on the public because it is beyond them to produce a regular, true blend, and the profit is larger, for cheap common Indians give out a strong, coarse liquor, without any quality, and make people for a time fancy they are getting a bargain, till they find out to their cost that Sir A. Clark is right. The leading medical men in England are condemning the use of Indian and Ceylon Tea alone, and the above extract from Sir A. Clark's lecture must convince all that a taste for Indians, which has to be acquired by force at first, is a serious and dangerous thing.

We are publishing the above extract for the benefit of those who have not seen it, and support what we have always maintained. This is against our own interests, for the profit on these Teas is equal if not more than that on other kinds.

Those, however, who know the colonies are aware that authority does not carry very much weight among the masses; and that there Jack is not only as good as his master, but a great deal better. Sir Andrew Clark may be a power among the dyspeptic and worn-out in the old country, but in New Zealand where the strongest and healthiest specimens of the Anglo-Saxon race are to be seen, it will amuse them to be told of "tea intoxication." The following is the reply from another trader who believes in pure Ceylon teas, and is very amusing. It is noteworthy that the London physician's name is slightly altered, and that there are more letters to his name than he usually rejoices in.

ANOTHER CITY IMPROVEMENT.

The Ceylon and India Tea Association have undertaken to provide the public with a means of testing the various grades of tea supplied by them. Their idea is to construct—and the carpenters and decorators are now at work—a large and handsomely furnished room at the back of their commodious premises

Princes street, where at a nominal cost a cup of y class of tea or coffee—as supplied by the Assoc.

* Another proof of how largely dependent our moral nature is on our physical, and of the importance of a good supply of oxygen or pure air.—Ed. T. A.

ciation—will be provided at a moment's notice. Waitresses will be in attendance, and every effort used to make "The Ceylon Kiosk" a favourite and convenient resort for ladies or gentlemen when in town. The attendants will be instructed to give every information—if solicited as to the class, price, and quantity of tea used, and the Association trust that this attempt to provide for the convenience of their present and prospective customers will be heartily availed of.

Eschewing all those attempts at presumptuous and impertinent coercion adopted by various aspirants for public patronage, with which all are now so familiar, the Association refrain even from following the example of that aged and eminent radical Sir Edwin Clark, M.P., F.R.S., F.R.C.P. (M.I.L.K.), for however desirous they may be to introduce and maintain their teas in public favour they dare not presume to dictate in a matter concerning which all are equally qualified to judge. All they do is to from time to time place the public in possession of certain facts—concerning which all tea experts are perfectly and unanimously agreed,—and acquainted with which every one can safely be left to use his or her own discretion and taste.

The soil of China has during many centuries been subjected to a continuous drain—without any opportunity for recuperation—of all the chemical constituents essential to the production of good tea, and is now so thoroughly impoverished as to be incapable of supplying the world with anything more than a mere weedy, sickly-looking representative of what should be a succulent and healthful article of diet. Ceylon, on the other hand, endowed with a rich and generous soil scarcely tested as yet, and in the hands of skilful and scientific cultivators, who can be relied upon not to exhaust, far less "kill the goose that lays the golden egg," is producing a tea so brimful of all that is appetizing and invigorating that it is scarcely astonishing to learn that old gentlemen unaccustomed to its strength have, like the poor old doctor Dr Edwin Clark, actually become slightly intoxicated by its use. The Association trust that the good citizens of Dunedin will not fall into the egregious blunder of mistaking the spurious article for the "Real Mackay"; not that we believe it possible that intoxication would result, but for the sake of avoiding waste, for every one should know that *Ceylon tea goes much further than China tea*, and consequently should not be used with the same liberality. The world, however, has passed judgment in the matter, and the result shows the verdict given—China's export is yearly decreasing, Ceylon's export is increasing by leaps and bounds.

TEA IN FIJI.—A Suva correspondent reports that the cultivation of tea is rapidly extending in the Fiji Islands. It has already been proved beyond doubt that the soil of these islands is capable of producing a very superior quality of tea, and some of the tea grown on the late Mr. Mason's estate on Tavium was regarded as equal to the best Ceylon of the time. Under Sir John Thurston's capable administration planters in Fiji are now surrounded with but few of the old difficulties, and there is no reason why tea and coffee should not become as good-paying lines as sugar in the islands.—*Colonies and India*.

CEYLON AND INDIAN TEA PLANTERS.—A correspondent writes to the *Englishman* and draws attention to the lamentable want of energy which has distinguished the Indian tea industry in its competition with Ceylon. Every device known to the "new advertising" has been employed in popularising the Ceylon product in the home market, and the methods which have proved so successful in London, are now being extended to Chicago with the view of securing a practical monopoly of the American market. As announced some months ago, the Ceylon Planters' Association has voted a considerable sum for the purpose of sending a representative to the World's Fair, who shall convert the free citizens of the United States

from their present faith in the Chinese product to an enlightened taste for Mazawattee; and the local Government has identified itself with the scheme by a grant of \$80,000. There is no reason to doubt that the ingenuity and enterprise which have procured for Ceylon tea a wholly disproportionate share of the English trade will be less successful in Chicago than in London. The American market is at present large, and the enormous increase of population gives promise in the future of practically unlimited expansion. Those who are interested in the Indian tea industry will have only themselves to blame if they are shut out in the future from their due share in the tea supply of the New World. The correspondent states that the Indian Tea Association is now collecting funds for the purpose of providing an exhibit of Indian Tea at the Chicago Exhibition, but it is doubtful whether, even with a contribution of from \$5,000 to \$10,000 from the local Government, the amount subscribed will exceed \$35,000. In view of the scale upon which the Exhibition has been conceived, this sum is, it need scarcely be pointed out, hopelessly inadequate. It is far less than the individual contribution of scores of enterprising firms; and if this is to be regarded as the maximum, Indian tea growers may be content to abandon the attempt to compete with their more enterprising rivals in Ceylon.

TROPIC AND SEMI-TROPIC FRUITS IN THE UNITED STATES.—For the first time the Census Office has made a special investigation for the purpose of ascertaining the extent and value of the production of oranges, lemons, figs, almonds, coconuts and other tropic and semi-tropic fruits and nuts as industries of the United States. The material from which the statistics contained in the Census bulletin just issued are compiled was obtained direct from the growers upon schedules specially prepared for that purpose and by personal visits of special agents to sections of the country where these products are grown. From the figures it appears that in addition to the tropic and semi-tropic fruits and nuts grown for home and family use in the United States there were in the census year 13,515 acres of almonds, 677.50 of banana, 169.88 of citron, 9,861 of coconut, 4,477 of fig, 550 of guava, 1,362.25 of kaki, 7,256 of lemon, 495.58 of lime, 12,180 of Madeira nut, 7,097 of olive, 184,003 of orange, 2,189.50 of pineapple, 171.89 of pomelo, and 27,419.50 of pecan trees, representing 658,566 bearing and 800,010 non-bearing almond trees, 577,782 bearing banana plants, 4,237 bearing and 14,110 non-bearing citron trees, 123,227 bearing and 1,199,519 non-bearing coconut trees, 138,186 bearing and 285,201 non-bearing fig trees, 32,943 bearing and 120,529 non-bearing guava trees, 58,300 bearing and 124,522 non-bearing kaki trees, 167,663 bearing and 498,784 non-bearing lemon trees, 19,069 bearing and 41,255 non-bearing lime trees, 188,409 bearing and 411,248 non-bearing Madeira nut trees, 278,380 bearing and 331,022 non-bearing olive trees, 3,885,890 bearing and 9,705,246 non-bearing orange trees, 21,750,000 pineapple plants, 3,279 bearings and 12,867 non-bearing pomelo trees, and 214,988 bearing and 657,980 non-bearing pecan trees. Excluding pineapples and bananas, which are all counted as bearing plants, as they commence fruiting within a year of planting it is seen that the average number of non-bearing trees is about double that of the bearing trees, the product of which in the census year was, as far as reported, valued at \$14,116,326.59, divided as follows.—Almonds, \$1,525,109.80; banana, \$280,653.75; coconut, \$251,217.41; fig, \$307,271.76; lemon, \$888,099.92; lime, \$62,496.90; Madeira nut, \$1,256,938; olive, \$386,368.32; orange, \$6,602,099.06; pineapple, \$812,159.17; pomelo, \$27,216; and pecan, \$1,616,576.50. On the basis of present prices, with all the non-bearing trees in fruitage, the next census ought to show a value of product of more than \$50,000,000. As a forecast of the future growth of these branches of horticulture, in addition to the acreage already planted, the number of acres of land in the United States susceptible of development in plant in any one or all of the fruits and nuts named has been ascertained, and the aggregate figures are also given in the same bulletin.—*London Times*, April 16th.

PROPOSED CINCHONA CULTIVATION
IN VICTORIA.

If ever it becomes worth while to cultivate the cinchona plants in Australia, a writer in the Melbourne *Leader*, whose article we reproduce, ought surely to have seen that the scenes of culture ought to be chosen in the tropical portions of Australia, Northern Queensland and the Northern Territory of South Australia. But if the enterprise has ceased to be remunerative in Ceylon, with its advantages of climate, labour and experience, it surely is not likely that the culture would pay anywhere in Australia with the wages of labour at a standard at least six times higher than that which prevails in Ceylon, India and Java. The interest of the question, therefore, for Australians in general and Victorians in particular is merely theoretical. The writer of the article had possessed himself of a copy of Mr. T. C. Owen's valuable manual of cinchona culture, published at the *Observer* office, so that the information he affords is generally correct. But there are exceptions; and how on earth the English Mr. Ledger, who gave his name to the richest of all the quinine-yielding barks, came to be transformed into "Mon. Ledger," would be inexplicable but for the fact that the chief names connected with the history of research into cinchona were French. The name of the Countess of *Chinchon* is wrongly spelt, after the error which Linnaeus committed and which has been perpetuated and will be, in spite of all Mr. Markham's protests. The name of Mr. McIvor of the Nilgiri plantations is wrongly associated with that of Mr. Gammie as connected with the manufacture of cinchona febrifuge, which, by the way, Mr. Howard did *not* recommend—quite the contrary—his commendation was confined to the qualities of the bark grown by Mr. MacIvor on the Nilgiris, especially the crown or officinalis barks. Mr. McIvor never took any part in the manufacture of a febrifuge from cinchona bark, experiments in that direction in Southern India being entrusted to a quinologist, criticism of whose work it is believed led to his suicide. Mr. Gammie of the Northern India plantations has been successful in the culture of the bark and in the manufacture from it successively of a mixed febrifuge and of pure quinine. Mr. McIvor, besides his success in the cultivation of the cinchonae, invented the process of removing alternate strips of the bark, which has been confounded by the writer in the *Leader* with the still better shaving process adopted by Mr. Moens of Java. The reference to the richness of the Ledger bark in Java, and the enormous profits from an acre of those trees, at first realized, reads now like a chapter of old world romance. Alas! for the glory departed and the profit which has ceased to be made from cinchona, over-production in Ceylon being the chief cause. We wish we could agree with the writer that there are any special evidences of improvement apparent. The use of quinine still needs to be popularized; but the preliminary of cheapening the product can scarcely be carried further than it has been, seeing that in less than a generation the price has gone down from £1, and 12s. per ounce to 9d! At that price it can scarcely pay the manufacturers, and certainly it affords no profit to the growers. Jamaica is not likely to occupy the field from which Ceylon, after an export of 16 millions of pounds of bark in one year, is gradually retiring. Java, which grows the very best quinine-yielding bark as yet known, is likely to be ultimately the source of the world's supply of the valuable prophylactic, febrifuge and tonic; and it will

certainly be cheaper for Australia to buy the product of her near neighbours in the tropic island of cheap labour than to attempt to grow and manufacture on her own account.

THE CULTIVATION OF THE CINCHONA.

Quinine is the medicine *par excellence* of the influenza epidemic, which for the last year or two has proved itself such a cosmopolitan curse to humanity. Whether owing to this fact, or to the success of individual experiments in cultivation is not ascertained, but it is certain that many inquiries have appeared of late regarding the probability of Cinchona, the quinine giving tree, proving a valuable addition to the products of Australia. A slight sketch of the history of this plant and of its varieties, as chiefly cultivated by Europeans, may therefore prove of interest to the readers of *The Leader*. Until a comparatively recent date Peruvian bark was the generic name of this invaluable drug, and chemists say it is still not infrequently asked for as simply the bark. This sounds commonplace enough, but the origin of quinine is nevertheless bound up with one of the most brilliant and romantic periods of the world's history. In 1532 the intrepid Pizarro, with a band of Spanish adventurers, descended upon Peru. Luckily for them they found the naturally rich and wonderfully developed country of the Incas a prey to civil war, owing to the great Inca when dying, having bequeathed a division of the kingdom which was foreign to customs. With his usual astuteness Pizarro at once decided to offer it as an "additional jewel to the already brilliant diadem of Spain." Seizing the advantage he therefore soon became master of the country, but before long insurrections, naturally incident to such a conquest, arose, and were suppressed with such incredible cruelties by the adventurers that Spain decided to form Peru into one of its South American viceroyalties. About the middle of the 17th century the Countess Del Cinebon, a very talented and shrewd woman, was at Lima with her husband, the then viceroy suffering from the fever of the country, an intermittent ague. She was much struck with the marvellous properties of a powdered bark procured from an indigenous tree, the Kina, thence quinine, and on her return to Europe largely exerted herself to secure a constant supply and encouraged its use among the fever-stricken people of the Spanish Vegas. In course of time Linnaeus, with due courtesy, in recognition of the immense service with the countess had rendered named the plant Cinchona, and under this name all the varieties of the tree since discovered or propagated are classified. While Spain held her ascendancy in Europe, quinine, as we shall now call the Kina powder, made rapid strides as an ingredient in fever medicines. Unfortunately, it was however, more or less a monopoly of the Jesuits; Protestants absolutely declined to be doctored by "Priests' powder," and thus the invaluable drug fell for almost a century into comparative disuse, attracting attention only through such channels as French quacks or advanced apothecaries. Italy has now perhaps the largest quinine factories in the world. Germany also absorbs large stocks of bark, chiefly for brewing purposes, but on the whole its place in continental pharmacy is still far too low. On the other hand, it attained about the end of last century a rapid celebrity among the leading physicians in England, and thus quickly as has been said, "opened up a new departure in the history of medicine." Its value in time of war and epidemics has long been indisputable, and now that it is the chief factor in grappling with the greatest posse reurgo of our time any effort which might eventually tend to cheapen or popularise the febrifuge should not lightly be discouraged. Seed or plants in wardian cases can easily be procured, and at a comparatively small cost, from India, Java or Ceylon, and there are portions of Victoria combining a free dry soil with sufficient moisture, which indicates the strong possibility of a suitable habitat.

To those interested in this remarkable plant, it may be of interest to trace some of the extreme diffi-

culties attendant on the first introduction of cinchona as a cultivation. Until recently South America was the sole, and often difficult and uncertain, source of supply, and while Spanish rule continued there the utmost caution was exerted, to prevent the Cinchona forest from being exposed to the curiosity or cupidity of foreigners. In fact, Markham, the greatest of all the authorities on cinchona, says:—"We did not even have a description of the Quinquina tree till Jussieu, the botanist, accompanied the memorable French expedition which went to Juito to measure an arc of the meridian, and so determined the shape of the earth. M. M. De la Coudra joined Jussieu, and for 15 years they remained toiling in the forests, only to be robbed of their plants in mistake for gold. Buenos Ayres en route to France. This was about 1735, and for about another 100 years the cinchona forests were all but forgotten, when it struck the Dutch Government that Java, being of a similar latitude and climate to Peru, might become a still more valuable possession to them if it could produce cinchona trees, the bark by this time having become a large and important article of commerce. Mons. Hasskerl, of the Java botanical gardens, was therefore despatched in 1853, with a permit and guide to the forests, but again comparative misfortune overtook the enterprise, for the guide wilfully or ignorantly misled him into selecting the seed of such a worthless variety, i. e., so poor in alkaloids, that even yet a watchful eye is kept to uproot any plant betraying by a grey hairiness beneath the petiole its inferior place in the genus cinchona. Since the discovery of the alkaloid quinine, and of several other less powerful alkaloids, such as cinchonine, in the bark, the bark itself has almost fallen into disuse powdered directly, and is therefore sold not as formerly, according to its regular and handsome appearance, but on the merits of sample analysis. Hence the extreme caution necessary in selecting for cultivation varieties which have proved themselves richest in alkaloids. Of all cinchonas yet known, the most valuable in this respect are the calizaya or yellow bark, and of these *C. Ledgeriana*, named from its importer Mons. Ledger, is so far supreme. It has this advantage, that while it not only secretes a very large percentage of quinine, it also does so in a remarkably pure state and in the outer cells of the bark.

The seed of this variety Mons. Ledger found very rare, even in South America, and a few years ago it was literally worth its weight in gold. In Java, where M. Ledger sold the bulk of his seed, the plantation from it proved one of the most successful undertakings on record. A paragraph from an interesting manual on *Cinchona Cultivation*, by Mr. T. C. Owen, Ceylon, the procuring of which should be the initial step in experimenting with the product, will give a fair idea of how valuable the Dutch have found this variety. Fourteen acres of *C. Ledgeriana* planted in 1866 showed "a return of 10,126 florins per acre during the seven years, from 1872 to 78, or 1448 florins per annum. In spite of this enormous return the plantation shows no signs of thinness, and were it now uprooted would give a return of at least £2,000 per acre. The bark of one tree of this remarkably plantation, No. 67, has been found to contain the wonderful proportion of 13 per cent. of pure quinine besides other alkaloids. Another 78, has yielded a bark containing 10.5 per cent of quinine, and no other alkaloid." This was written before the very considerable fall in the price of bark, but as he goes on to say "By the method of harvesting now employed, this result will be greatly increased," the immense value of healthy plantations of a good variety of Cinchona is even now indisputable. The method of harvesting alluded to by Mr. Owen was invented by Mr. Moens the director of the Java plantations, and is both curious and interesting. It is a system of removing the bark in strips from the living tree. This is done by a set of spoke, shaves so regulated that whether operating on a thick or thin bark the knife avoids fenceling the cambium, or layer of mucilaginous viscid matter, which is intercepted between the wood layers and the bark. When care is exercised in this particular, not

only does the bark renew, but also secretes even a larger percentage of alkaloids. A covering of rough grass is usually tied over the wound to protect it from the sun. On account of the Dutch success in Java a proposal was in 1853 laid before the Indian Government to attempt a similar undertaking. It was calculated that 1,000,000 of people died annually of fever in India, and that nearly a half of their lives, besides an incalculable amount of suffering, might be spared if only some low priced alkaloid could be made available in every village. The laudable idea was therefore seized upon with enthusiasm, and the Government spared neither time, trouble nor expense, even to a special steamer to carry the collections directly across the Pacific. Mr. Markham happened at the time to be exploring Peru in search of objects of an antiquarian and ethnological character, and to him, assisted by Mr. Cross, was entrusted the great undertaking. At much personal toil and peril they penetrated the vast primeval forests, carefully studied the conditions under which they found the parent trees growing when they collected seed, as well as the soil and temperature natural to the various varieties, persevering through every difficulty and discouragement till they had not only succeeded in establishing the now world renowned Government plantations of India, but also, as at a later period, in conjunction with such men as Messrs. M'Leor and Gammie, found those factories which work up the so-called inferior alkaloids into febrifuges inexpensive enough to be within reach of the poorest villagers. Howard, the great quinologist, expressed the highest opinion of some of these preparations. These are yearly improving, as factories increase, which is especially the case since Government, meeting the complaint that they were competing with private industry in this cultivation, withdrew their bark harvests from the open market, and with great fairness agreed to use up Government bark for Government purposes only. South India and Ceylon have been the great centres of private enterprise in the east. There is some cultivation also in Bolivia and Peru, while in Jamaica it is under the auspices of the Government, who were fortunate in securing as director Mr. D. Morris, F.R.S. Besides his general extensive knowledge of botanical subjects he took very special knowledge of cinchona cultivation with him from Ceylon, and Jamaica now bids fair to be the quinine producing country of the western hemisphere. Some of the hardier varieties have grown and harvested in Ceylon at an altitude of over 5,000 feet above sea level. It has been a rule there to avoid any appearance of a damp subsoil, and some of the finest trees to be seen in that island are on poor ridges of moist districts. The experience of cinchona cultivation among the hills of Ceylon would therefore, of all cultivating countries, be the safest basis for Victoria experiments. From large stock of bark flooding the market, and including a South American bark called Cuprea, of which it was said there was an inexhaustible supply, cinchona bark fell suddenly and disappointingly, so that even yet only the finer classes pay. The South American indigenous supply is, however, failing, and till lately little effort, if any, was made to restore the forests. Cuprea has been proved to secrete a very small quantity of quinine, and from its hardness presents so much difficulty in extracting the alkaloid that it can only come freely into the London market when prices are high. Ceylon has chiefly turned its attention to tea, and as has been said, the Indian Government uses its bark for Government purposes. The product is thus bound ere long to find its true level again, and any serious check to its production would be an incalculable loss to humanity and to the human creation. The boon of a cheap effective febrifuge has yet to be placed within reach of the ordinary veterinary surgeon. Quinine, the only specific yet known for malarial fever, must first find its way to the terrible coasts of Africa, to the fever stricken portions of America and North Australia, and the day is also likely to come when quinine will replace opium, now the least expensive, but most ruinous of fever cures among the teeming millions of China. Wherever, therefore, it is

found that cinchona can be successfully grown, the industry should meet with the strongest fostering encouragement. As the cultivation requires little labor, and as there are districts where both soil and temperature point as very possibly suitable to the product, there appears no reason why Victoria should not yet possess successful cinchona plantations.—Melbourne Leader.

THE TEA FUND: CEYLON TEA IN RUSSIA.

Mr. Philip Secretary to the P. A., sends us the following copy of a letter received from Mr. M. Rogivue on the subject of pushing the sale of and making known Ceylon tea in Russia:—

TEA FUND.

(Copy.)

Moscow, March 1/13 1892,
Maroseika, House Lebedieff.

A. Philip, Esq., Secretary to the Planters' Association of Ceylon, Kandy.

Dear Sir,—I beg to acknowledge receipt of your favour of the 29th January, annexing copy of resolution passed by the Standing Committee of the Ceylon Tea Fund on the subject of further assistance to be given to me for the pushing of Ceylon tea in Russia.

It would have given me great satisfaction if your Committee, in acknowledging my last report, had expressed an opinion, good or bad, as regards the work and progress I have done during the 10 months in 1891 I reviewed, because, as it came to my knowledge, some indirect remarks have been made as to the relatively small quantity of tea sold by me in the course of that time. The spreaders of these remarks seem entirely to forget that before I came to Russia, no such thing as Ceylon tea was drunk nor a pound of it was sold *pure* in the country, whereas now, if I am well informed from high quarters in London, 400 to 500 chests are shipped weekly from London to Russia. Custom House statistics may be consulted in London; and as I have already mentioned the fact, it is clearly noticeable that large quantities of Ceylon tea are now used in Russia for the blending of cheap and inferior Chinese. As far as I am concerned, I will repeat what I very often said the ways and means of *selling* this tea are no difficulty for me to find, but the means of *getting it duty paid* in sufficient quantity is the chief obstacle I meet with to increase its sale.

More *reclame* must be done and more tea ought to be placed at my disposal, as my capital is not sufficient to extend now my business. I have been trying lately, with the help of some friends in London to form a Syndicate with the necessary capital required for the extension of the business (borewith for your perusal copy of my prospectus), but the present unfavourable financial circumstances all over Europe seem to be against the realization of my project. Should it perhaps be possible to manage such a scheme in Ceylon or to induce some Ceylon planters (proprietors of tea estates) to consign to me, for sale on their accounts, some of their invoices according to the instructions I could give them as regards the qualities suitable for the Russian taste, or to standard samples deposited as reference in the hands of the Colombo tea brokers, shipments could be made direct to Odessa, or via London to St. Petersburg, Revel or Liban, and no doubt the shippers of such breaks would find their advantage in selling them thro' through me by retail and for wholesale combined.

Since my last report, I have sold monthly the following quantities:—

November 1891 Russ. lh. 3,395	} 13,933 lb.	
December " " 2,967		
January " " 3,689		almost all
February " " 3,882		in packets.

which figures, although December was a small month on account of the holidays during which time business was closed, and notwithstanding my already mentioned difficult financial circumstances, still show a small increase over the preceding months, and make the

total quantity sold *from my magazine only*, almost all in packets, over 40,000 lb. for 12 months out of 50,000 lb. I have imported; and it is important to remark that these 40,000 lb. were all of *pure Ceylon tea* which have gone in the Russian consumption.

My Nishny magazin is doing very well indeed selling *presently* an average of 1,000 lb. per month and had I had larger quantities duty paid, to put at that market, I would I am sure, have tripled the quantity.

I am now making arrangements for the fair to be held next July and have already secured a magazine at the "Fair Town" where I ought to sell if the provisions of my own people are not exaggerated, something like over fifty thousand pounds tea, as many merchants from several parts of the country have promised to buy it.

But to be able to do this, it is absolutely necessary that sufficient stocks are kept at hand, in the Moscow Customs, that sufficient funds are at my disposal for the clearing of the tea whenever required, and that some more money should be spent for *reclame*. At the last Nishny Fair, I missed many good and important sales for the want of *available duty paid stocks*, and it is indisputable that if we gain the public and the merchants to purchase our tea *at the Fair*, we will have gained the whole of Russia.

Some facts worth mentioning as a proof that Ceylon tea has already a good name and is making its way into the country are the following:—

During a recent visit I made in Nishny one of my regular clients there, proprietor of a tractor, told me that when he was formerly using Chinese tea he cleared a profit of R4 per lb. whereas now since he has replaced it by "Ceylon" his profit is R8 on every pound!

I heard lately from Saratov, where my tea is sold in packets on a pretty large scale, that same retailer to whom I refused credit is now selling a bad imitation of Ceylon tea in packets. And it will perhaps interest you to hear that my Ceylon tea is going as far as Siberia.

In conclusion I will again try to impress upon your Committee, and every Ceylon planter, the interests of whom I have greatly at heart, that, although I am certain and very sanguine that the sale will greatly and rapidly increase as soon as I can overcome the financial difficulty for the pushing and extension of my operations, a great deal of work is still to be done in order to attain the desired results; and trusting that the Tea Fund will not only reimburse me my over-expenditure as per last accounts rendered, but also continue to give me further assistance for any work of *reclame*, and the welfare of my misdeu, I remain, &c., (Signed) M. Rogivue.

"THE INDIAN IMMIGRATION ORDINANCE A BURDEN."

(To the Editor of the "Pinang Gazette.")

Under the above heading you reprint, in your issue of 23rd instant, a letter written to the *Straits Times* by Mr. E. V. Carey, the sum and substance of which is that "either the agricultural development of the Malay Peninsula must be retarded or free immigration must not only be sanctioned but, be supported by Government."

How far immigration is supported by Government is doubtful; but that free immigration is sanctioned, Mr. Carey himself admits when he complains of its being "the duty of the Immigration Agent to board steamers and explain to immigrants that they are quite free." Mr. Carey's interpretation of "free" is, I presume, when coolies are given an advance in India by a "reliable agent" and brought over under a verbal contract to work it off. These coolies must not be told by the Immigration Agent that they are free, but the "reliable agent" must be allowed to take them off to work for years on some out of the way plantation, where he supplies them with the necessaries of life so long as they are able to work, and even gives them a few cents on rare occasions with which to buy petty luxuries from himself at five times their value. The balance of their 25 cents per day wages they are told goes to pay off coast advances with interest.

The disclosures made in Ceylon some years ago will surely prevent this mode of immigration being substituted even for our present one. Had Mr. Carey taken the trouble to visit the Province Wellesley estates and seen the contented and prosperous condition of the Tamils, both indentured and non-indentured then he could never have written as he has done, no matter how great a sensationalist he may be, nor would he have said that the coolies are underpaid. There is nothing to prevent Mr. Carey increasing his rate of pay as much as he likes, and he can easily get protection for his "reliable agent" in India by getting recruiters' licenses for them; so what more does he want? If the coolies are free, there can be no harm in telling them so.

It is an old story about the minimum rate of wages being fixed to suit the Province Wellesley sugar planters, but perhaps Mr. Carey is not aware that Government did that on account of the planters' good looks (*sic*). It ought to have been altered long ago in favour of Ceylon coffee planters, but Government is so old fashioned that it sticks to a tried and trusty friend in spite of the attractive gilding which Mr. Carey has given to Ceylon's output—coffee.—I am &c., Caledonia, 25th March 1892. JOHN TURNER.

CEYLON TEA IN AMERICA.

Mr. R. E. Pineo sends us a copy of the *Washington Post* of 10th Feb. containing the following:—

THE WHITE HOUSE TEA-CADDY.

The Elephant's Foot from the Island of Ceylon.

One of the most unique as well as interesting articles to be seen in the family dining-room at the President's house is an immenso elephant's foot which is devoted to the purposes of a tea-caddy. Inside a silver lined box reposes some of the finest Bhud tea ever produced, and which was sent from the Island of Ceylon, where it was grown under the auspices of the Planters' Tea Company of that place.

For a week past frequenters of the mammoth fancy groceries establishment of John H. Magruder on New York avenue, near Fifteenth street, have noted a magnificent window display under the direction of a representative of the Ceylon Planters' Tea Company. Two natives of the island—a man and a woman—the latter said to be the only one of her sex who has ever visited this country, have presided over and dispensed the cheering beverage. Attired in the costume of their country, these people have attracted a great deal of attention, the woman in particular coming in for a large share, by reason of the ornaments used by her in bedecking herself. On the left side of her nose a hole has been bored, from which there is a pearl suspended, the gem being one of the finest for which the Island of Ceylon is noted. Her costume is a bizazro, but effective one, in which red silk and gold lace and fringo predominate.

Incidentally the islanders are useful in handling the wares called Bhud, Tiffin, and Bungalow, which the company is just introducing to public notice. Accompanied by Manager Beireck, they called upon Mrs. Harrison at the White House and were accorded a gracious reception in the Blue Parlor, a privilege which they seemed to appreciate very highly. For the next week or so the exhibit of the tea company will continue at Mr. Magruder's up-town branch store, No. 1122 Connecticut avenue, where samples of this valuable commodity will be shown and its merits explained. Ceylon Bhud, Tiffin, and Bungalow tea enjoys the distinction of being the best flavored of all teas, and it excels the products of China and Japan so much that it has drawn a large proportion of those teas from the English market.

The same paper contains an account of a State reception by President and Mrs. Harrison, at which Mr. and Mrs. Elwood May were present. The following paragraph is devoted to them:—

Mrs. May wore a gown of black velvet profusely trimmed with rare old family lace, her jewels being

rubies and pearls from the Island of Ceylon. Mr. May has recently returned from abroad, where he was entertained by many of the English nobility.

Mr. Pineo also sends us a copy of the *New York Mail and Express* of 12th March, containing the following as an advertisement:—

FROM THE ORIENT.

Any one visiting the Health Food Exhibition at the Lenox Lyceum will notice with considerable interest the Orient exhibit of the Ceylon Planters' Tea Company, famous for their "Bhud," "Tiffin" and "Bungalos" brands of tea. They occupy alcove D, which they have turned into a veritable native bazaar, decorated profusely with cloths and ornaments from the island of Ceylon.

Among many curios we notice an elephant's fore-foot made into a lady's workbox; the companion of which was presented by the president of the company, Mr. S. Elwood May, to President Harrison, filled with the choicest tea valued at \$183 a pound.

Among the pyramids of tea, which consists of over 5,000 packets, three native Ceylon servants of the company's in full Oriental costume, glide gracefully in and out, serving to all who desire cups of "Bhud" Tea, celebrated throughout the world for its refined and delicious flavor, and also is a nerve tonic, owing to the soil upon which it is grown being very strongly impregnated with iron. Hence upon all their advertisements appear their insignia "Nervousness farewell."

It is not generally known in America that the planters of the island of Ceylon are younger sons of English noblemen, and gentlemen, invariably graduates of Oxford, Cambridge, Harrow and Eton. Educated and intelligent, they have advanced methods and have invented their own machinery, so that the tea is now untouched by hand from the time of plucking.

As the writer was enjoying his cup of tea he overheard one of the representatives of our old Knickerbocker families say: "Everything connected with the Ceylon Planters' Tea Company is of the highest order, their 'Bud' tea and 'Lanka' coffee, their picturesque servants, their advertisements, etc." Her companion, an English lady, replied with a touch of national pride, "There are interested in this company in England such gentlemen as Sir Arthur Birch, K.C.M.G., late Governor of Ceylon, now manager of the Bank of England; Right Hon. Sir Wm. Gregory, K.C.M.G., twice Governor of Ceylon; Sir Arthur Gordon, G.C.M.G., late Governor of Ceylon; Sir Roper Lethbridge, K.C.I.V., M.P.; Sir James R. Longden, K.C.M.G., late Governor of Ceylon; Sir Richard Cayley, late Chief Justice of Ceylon; Sir G. H. D. Elphinstone, Bart.; Gen. Sir Redvers Buller, V.C., K.C.B., K.C.M.G.; Gen. Lord Chimsford, G.C.B."

It is well worth a visit to the Health Food Exhibition to see the picturesque Ceylonese in their Oriental splendor. Their jewels are heavily antique wrought and set with precious stones. The pearl the woman wears in her nose ring is very valuable and one of the finest small specimens of the island.

The *Mail and Express* of 14th March gives an account of a dinner to the President's son; and it is stated:—

"Among the guests was S. Elwood May, of New York, president of the Ceylon Planters' Tea Company, of which Mr. Harrison is a large stockholder" &c.

In this connection we may quote as follows from the letter of a correspondent:—

"I think Mr. Lipton's statement in his recent letters should not go uncontradicted about the Tea Company not having advertised. Mr. Lipton was there on September 8th. Possibly the large advertising contracts (190,000 dollars worth) have been entered into since then. Mr. May sent you on 5th February a lot of newspapers, journals, &c., in which the Company were advertising."

We take blame to ourselves for not having corrected Mr. Lipton's erroneous statement.

CEYLON TEA IN RUSSIA: ANOTHER LETTER FROM MR. ROGIVUE.

The Secretary of the Planters' Association sends us the following copy of a further letter with enclosure received from Mr. M. Rogivue on the subject of pushing the sale of and making known Ceylon Tea in Russia:—

Copy. Moscow, 7, 19th March 1892,
Maroseika, House Lebedieff.

A. Philip, Esq., Secretary to the Planters' Association of Ceylon, Kandy.

Dear Sir,—In continuation of my respects of the 1st/13th inst., I herewith beg to hand you the copy of a letter from Mr. Milowidoff, the Assistant in charge of my permanent Magazine at Nijini-Nowgorod, giving his appreciation as regards the further extension of Ceylon Tea in Russia and the steps to be taken in view of the coming Fair.

I shall thank you to submit the same to the Committee of the Tea Fund.—I remain, &c.,

(Signed) M. Rogivue.

I enclose one of my new Price Lists.

Copy of a letter of M. Milowidoff in charge of M. Rogivue's Magazine in Nischny Nowgorod.

Nischny Nowgorod, March 2nd, 1892.

Translation.

Enough time has elapsed since the Nischny fair of 1891 took place to enable me now to form an opinion as to the future "Ceylon Tea" is going to have on the Russian markets.

The Nischny Fair has been the touch stone of Ceylon tea, when already a large number of persons were eager to try this new product. It is true that the business of the fair did not, relatively, get to an important extent because most of the people bought this tea merely as samples, with the chief object to taste it. But the results of the fair have nevertheless been very satisfactory, thus proving above all what a good *réclame* it has been for the tea; the merchants, the public and the newspapers having already taken a great interest in this tea, quite new in Russia.

From the Nischny Fair and later on from the Nischny Magazine Ceylon Tea has been sent to the most remote places of the Country: *Valoia, Astrakan, Niakha, Orenburg, Kostroma, Ufa, &c.* We have every reason to believe that the tea made a favourable impression upon the general public, and this because, just after the Fair, many of the former buyers renewed their purchase and new clients came forward. In short, the fact that Ceylon tea is making by degrees its way amongst the public of Nischny accustomed to drink good tea, and spoiled in this respect thanks to the Fair, this fact, is a guarantee for its brilliant future. The Nischny Magazine although only opened since six months may safely be expected to sell 12-15,000 lb. in this year, without bringing in account the quantity liable to be sold at the Fair. This, I think, is another striking proof that this Tea is already known and appreciated. If the Nischny Magazine balances the accounts of this first year with perhaps no profit or even a small loss, the following reasons may be accounted for: 1st the novelty of the business, 2nd the high rate of gold, 3rd the expenses caused by the installation of the magazine and 4th the occasional want of stocks which have sometimes failed. As you know it very well, we have been and we are still very often obliged to refuse sales, giving for instance 5 lb when 50 lb. are asked; this of course has made a bad impression, shaken the credit of the firm and driven away numerous clients. I can boldly assure that the Nischny Magazine would have sold twice the quantity if the goods had been readily at hand.

To my opinion, Ceylon Tea will spread fast enough and considerably under the following conditions: 1st if it is sold *cheap* enough to compete for prices with Chinese Tea; 2nd if a thoroughly good *réclame* is done; 3rd that the Nischny Fair be well conducted with sufficient quantities; and these conditions are all indispensable for the success of

the Fair and the further extension of the tea. Judging by the results of the first Fair and of the magazine, one can safely presume that the demand at this year's Fair will considerably exceed the last one. It is therefore necessary that larger stocks should be available. I should say that for the Fair alone we must have at least 100 cases* of different marks, besides about 5,000 lb tea in packets, not speaking of larger orders (orders exceeding 5 cases of one sort) which will be executed in Moscow where sufficient stocks should be kept. I will repeat that the *réclame* is absolutely necessary for our success and I would suggest that a sum of about 500 Rbs. should be assigned for this purpose. The Nischny Fair is the centre of the whole of Russian trade; amongst the heap of all kinds of new products brought on this market it is easy for an article to pass unnoticed and this is the reason why *réclame* plays such an important part. Every firm starting business there spend up to thousand roubles in advertisements and the expenditure is justified. I would propose to begin advertising in the newspapers of the provinces, already before the opening of the Fair. Another way to increase the sale of Ceylon tea would be to open, after the fair, new magazines in one of the towns on the Volga, *Kazan* or *Saratow*, as branches of a well established firm are the safest and the best factors of a good *réclame* the establishment of which would cost about 3,000 Rbs. per annum. These outlays would certainly be covered, and largely, considering that if at Nischny, a relatively small town, where business is not so important, the expenditure is covered, one can the more so reckon on *Kazan* and *Saratow*—important commercial centres on the Volga, three more populous than Nischny.

I found it is necessary to account you with my ideas in view of the coming fair so that you might see what you are about and take in due time the necessary steps.

(Signed) MILAWIDOFF.

LADY TEA MERCHANTS IN LONDON.

Women are generally credited with being the greater tea drinkers, and men, when they wish to retort on being accused of smoking too much, answer that tea takes the place of tobacco amongst the luxuries appertaining to the gentler sex. This may or may not be, but in either case it seems that there is little or no reason in these days of womanly enterprise why ladies shouldn't not be purveyors as well as consumers of tea. This thought appears to have struck two ladies who have for some time been doing good business in quite a private way in this most necessary article. Under the title of "The Ladies' Own Tea Association, Limited," a Company has now been formed and registered, consisting of seven lady shareholders, and directed and managed by the two ladies who originated the scheme, Miss R. G. Bartlett and Miss A. M. Lambert. Premises have been taken at 92, New Bond-street, where the tea association may be seen in full working order. There is an office—or, perhaps, to be perfectly accurate, a shop—fitted up with every requisite for the blending and tasting of tea. A counter as bright as polishing can make it, gleaming brass scales, and tin scoops; tin cases to hold five, seven, and ten pounds, huge layers of brown paper, and paper bags, all proclaim the business-like nature of the enterprise; whilst an inner room, fitted with the pretty tables, Japanese ware, Oriental rugs and matting, and the soft-toned draperies we associate with high art, invites lady customers to partake of a refreshing afternoon cup. These are some of the aspects of this latest development of feminine industry. Its objects are primarily to provide a new employment for necessitous gentlewomen at their own homes by establishing agents (who must be ladies) in every town, district, suburbs, and village of Great Britain and Ireland. Secondly, to sell the best tea at a low price. This can only be achieved

* Duty paid (costs by M. R.)

by importing the goods direct from the estate, which is in Ceylon, and thus avoiding the possibility of adulteration and the profits enjoyed by the middleman. Besides, the fair agents there are to be bleeders, packers, and sellers of the same sex, and the promoters are most anxious to make the Association known as widely as possible, in order to benefit all those for whose benefit it is intended. Although the Association especially recommends the Ceylon teas, it supplies various other kinds and blends, thus suiting the tastes of all customers. It is always said that Ceylon tea is more wholesome and much cleaner than that of either China or Japan as it is prepared entirely by machinery and not by the hands and feet—frequently unwashed—of the natives. The prospectus issued by the Company contains a few hints on the brewing of tea, and there is no doubt whatever that in many households these hints are as most necessary. The terms of the "Ladies' Own Tea Association" are strictly cash, and the prices vary from ls. 8d. to 4s. Orders of seven pounds and upwards will be delivered carriage free to any part of the United Kingdom, and those for less than that weight will be sent subject to the usual Parcels Post rates. Sample packets of 14 ozs. will be forwarded post free for the price of 1 lb. Should a chest of 10 or 20 lb. be required, it can be packed on the estate itself and sent direct and unopened to the purchaser. No agent incurs any liability, and the principal injunction is that the must always deliver each parcel to the customer unopened and in the condition in which it is received from the Association. Also that small weekly orders should be accumulated at least to the amount of 7 lb., which will be sent free to the agent for distribution amongst the purchasers. Any agent who is not able to dispose of five pounds of tea per week will be disqualified, and another appointed for that District. Good commission is paid by the Company, and the amount of it is forwarded every Saturday to the agents. At Christmas a bonus of 2½ per cent. is given on the amount of commission obtained during the year.—*M. Mail.*

MR. WILLIAM JACKSON.

[We greatly regret the delay in republishing the following memoir of Mr. Jackson, the great tea mabinist, which appeared, with a very good likeness, in the *Indian Planters' Gazette*. Illness, from which even newspaper editors are not exempt, must be our excuse for overlooking this and perhaps some other matters, in the avalanches of "exchanges" which reach us from all parts of the world.—*Ed T. A.*]

We have already given our subscribers the portrait and history of more than one tea-planter whose inventions have made them famous, and the fact of the original of this picture being on a visit to India enables us to publish the following sketch of a gentleman whose wondrously clever patents have made him deservedly renowned wherever the tea industry flourishes.

Mr. William Jackson was born in 1819 at the farm of Davo, on Lord Kintore's estate of Kethall, in Aberdeenshire, Scotland.

At the age of 6 years his father died and he remembers little of him; but in after life was told by his mother that his father had more than once remarked, "We will make something of that laddie yet."

His most vivid recollection of early life was about the age of 10 years. About this time he fell a victim to typhoid fever, and when sufficiently convalescent to be getting about, a portable engine and thrashing machine was for the first time brought to the farm to thrash the crop, and the engine-driver's name was George Wood.

Being fascinated with the engine and not strong enough to move about, a "winlin" of straw was placed near the engine for him to sit on and he so plied "Goordie Wid" with questions, that his patience

got exhausted and he was told "If ye spere ony mare questions I'll pit ye in the furnace."

Being enamoured with the wheels and belts, nothing would now satisfy him but make a working model of a thrashing machine, and this he so constructed in a very primitive way in the carpenter's shop and smithy, which were on the farm for roairing and sharpening agricultural implements, and the belt was passed over the grindstone to gain the necessary speed on the drum, the farm servants willingly driving the handle on the summer evenings; whilst moss plucked from the roots of trees was passed through the small machines, the sand and grit coming out as the corn whilst the mess was delivered as straw.

Mr. Jackson's eldest brother James, and whom he describes as one of the worthiest men who ever lived, now came of age, and took over the management of the farm, and seeing how hopeless it was to keep him out amongst whols, set to work and got him into Messrs. George Murray & Co.'s iron foundry at Banff, on probation.

In the meantime an excellent neighbour, Mr. Bisset of Artanbio, and a Mr. Annand of Inverurie, thought that Willie Jackson should serve his time in a more advanced engineer's shop than that of Banff, and on their own account went to Aberdeen and obtained from the celebrated firm of Messrs. Hall Russell & Co., engineers and ship-builders, an apprenticeship for him.

From this time onward Mr. Jackson remembers all that happened to him. He quickly showed abilities above the average apprentice, and long ere he had completed his 5 years he had individual responsibility placed on his shoulders, and on the completion of his time, Mr. Russell, the manager, was most unwilling to let him go, and wages were offered much in advance of the usual as an inducement for him to stay; but Mr. Jackson was bent on foreign lands, and nothing would then alter his decision to go abroad.

His brother John was at this time Manager of the Scottish Assam Tea Co. in Assam, and had suggested Calcutta as a likely place for him to come to. On reaching this Mr. John had a letter waiting for him, stating that if nothing turned up suitable to come on to Assam, and probably he might become a tea planter.

Nothing suitable was found and Mr. Jackson went off to Assam, and singularly enough to say, Mr. William Lawrie, now the successful Manager of the Jhanzio Association, was then assistant to Mr. John Jackson, and a week before Mr. William Jackson's arrival resigned his appointment to take the management of the Loajan Estate, and Mr. John simply put his brother in Mr. Lawrie's place. Mr. Jackson relates rather an amusing incident of his first experiences of Assam life. When he reached Kookleamook, the steam boat station on the river, it was about 4 p.m., and a letter awaited him from Mr. John giving instructions to put himself in the bearers hands who would bring him safely to Mazengah. This was done and the first two hours were spent in a dug-out boat which took him into a *bleel* or shallow piece of water, the edges of which terminated in mud in which the buffaloes wallow.

Here an elephant was waiting him which was brought alongside the boat and caused to kneel down in the mud for Mr. J. to mount.

On attempting to do this, however, the monster beast trumpeted so loudly, that Mr. Jackson made a bounding leap, and landed himself headlong in the mud and water as far from the boat and boat as he could, out of which mess he was lifted by the coolies and put on the *hattie*, and in this state reached Mazengah about 10 p.m. little or none the worse of the fright he had got.

Mr. John Jackson about this time had decided on manufacturing all the leaf at Ilehakah, and resolved on making this a central factory for the whole of the Company's gardens; and as a consequence Mr. William was transferred there with himself and got charge of the tea-house and the making of the tea.

The leaf now being all brought to one centre for manipulation greatly increased the work to be accomplished in the tea-house; and as there was only a two plated Kinmond's roller, which only partially rolled the

leaf, and a very small engine to work it, Mr. Jackson's duties often extended far into night, and it was this and this alone that gave him his first start in tea machinery.

He made his first resolution in the lonely midnight hour that he would produce a machine that would do the work as to give him time for sleep at any rate, and before 3 a.m. next morning he had made a model disclosing exactly the motion imparted by coolies in rolling leaf on tables by hand.

On showing this to his brother permission was given to make a machine, which in course of time was done, and proving a success it was thought desirable to patent it.

The patent specification was crudely drawn up, and as most of our readers will know was subsequently the subject of much and severe litigation between Mr. Jackson and Mr. Kiumond.

Mr. Jackson has much gratification in the fact that some of the very first rollers he made have stood the test of a more than 20 years' work and are well spoken of at the present day. Soon it began to be known that a new roller had been invented that would actually finish the rolling of the leaf, and orders began to come in; but who was to make the machines?

Mr. John Jackson at this time resigned the management of the Scottish Assam & Co. and returned to Scotland, and with him took some 8 or 10 orders for the new roller, but singularly enough to say much difficulty was found in getting any firm at home to make the machines. No engineers of standing had ever before heard of tea machinery, and it being quite a new venture, as they termed it, one after another declined to take it up, till at last a firm in Glasgow was prevailed on to make them. They made about 60 rollers in all, when Mr. Jackson went home and to his great delight got Messrs. Marshall Sons and Co., Ltd., to take up the manufacture of them, and from that day to this Mr. Jackson has been able to give Planters the highest class machinery.

Everything now went well till the crash came with Mr. Kiumond, which swept all from under the brother Jackson's feet and caused a dissolution of partnership, Mr. William still holding on to it, whilst Mr. John retired and went to America.

Mr. Jackson had a long and severe struggle to regain lost ground and speaks very feebly of Messrs. Marshall Sons & Co.'s, Messrs. Balmer Lawrie & Co.'s, and the Planters' great kindness to him at this time, and says he could not have survived the blow but for them.

The single action and Standard Rollers had up to this time been his productions. The Standard Roller, although a good machine, was expensive in construction, and for a considerable time in his home in Aberdeen Mr. Jackson had been thinking of a possible mechanical means of producing a less costly machine that would have the same action on the leaf as the Standard Roller. Careful thought thus produced the well-known Excelsior Roller, the peculiar crank motion of which is said to be unique in the list of mechanical movements.

Having now got a good roller Mr. Jackson began to turn his attention more closely to Drying machinery, but it is only within the last 5 or 6 years he has given special thought to it, and in this short time it surprises us to learn he has sold over 500 Victorias, 300 Venetians, and since May this year, when his first new Britannia Drier was started in Ceylon, something close on 100 orders have gone home for them, and from all we hear of this fine new machine he is likely soon to creep on to the four figures with it.

Mr. Jackson also surprises us by stating that there are some 50 patents granted in Calcutta alone for rolling machines, and with a me feeling of pride says:—"I think I am the only one who has come through from the start in Tea Machinery," and expressing great thankfulness to genuine old friends still in Assam and Ceylon, who have supported him through good and bad times, he still hopes for many years to devote his whole energy to the development and improvement of machinery used in the manufacture of tea.—*Indian Planters' Gazette.*

NOTES ON PRODUCE AND FINANCE.

TEA AND TANNIN.—Life would be monotonous if it were not for the flip given to it by those little alarmist rumours with which the medical papers beguile the weary hours and excite the imagination of their readers. These who gape for the lack of something to do, and must have a new sensation at any price, find the first moment of a startling announcement positively exciting. Between the *Lancet* and the *British Medical Journal*, the average human being who eats and drinks food subject to analysis may always feel on the *qui vive*, is so disposed. The *British Medical Journal*, for instance, in the course of its researches into the mysteries of tannin in tea, and in that of China in particular, as compared with teas of Indian and Ceylon growth, gives the following result:—"China, 7.44 tannin, 3.11 theine, 30 minutes' infusion; Indian, 17.73 tannin, 15 minutes' infusion; Indian and Ceylon blended, 10.26 tannin, 8.91 theine, 15 minutes' infusion." If this be correct, the Indian and Ceylon teas appear to contain nearly double the quantity of tannin to be found in China tea, even when the latter is infused for a much longer time than the former. The *British Medical Journal*, in the article referred to, says:—"Some examples which have been forwarded to us of the results of analyses for tannin and theine in tea indicate considerable variation in the amount of tannin, according to the quality of the tea and the stage of growth at which it is picked. In some blends of China teas the percentage of tannin extracted by infusion for thirty minutes was 7.44; theine, 3.11; and a similar result was given in the examination of the finest Moning; while, on the other hand, with fine Assam tea a percentage of 17.73 of tannin by weight was extracted after infusion for fifteen minutes; and two blends of Assam and Ceylon tea gave respectively 8.91 and 10.26 of tannin. On the whole, it is probable that the Indian teas are much more heavily loaded with tannin than the China or Japan teas. Moreover, the common method of prolonged infusion in boiling water is well calculated to extract all the tannin, while it dissipates the flavour of the tea. To be drunk reasonably, tea should not be infused for more than a minute, and with water of which the temperature does not exceed 170° Fahr. It should be taken without sugar or milk, which would drown the flavour of the delicate and aromatic infusion thus obtained. This, at least, is how tea is drunk both in China and Japan, whence we have borrowed the use of it. With our European method of prolonged infusion in boiling water we destroy all the best flavour of the tea, and we extract such heavy proportions of tannin as to cultivate indigestion as the result of tea-drinking. Indigestion is unknown among tea-drinkers in the East, and it is, in all probability, only the result of our defective use of the leaf." The idea of tea infusing for one minute only is certainly novel, and will amuse Mining Laue. As for the consumers of tea, they will, no doubt, with that perversity which characterises the victims of a bad habit, continue to drink tea infused as usual, audaciously selecting the teas of India and Ceylon in preference to those of China, because the former are stronger and give better value for the money.

TEA PLANTING AND TEA RETAILING.—The sequel to the brief correspondence which appeared in our columns about two months back about the advantages—real or imaginary—which the grocer who was himself interested in tea gardens possessed over the tea retailer who was not is now to be found in the prospectus of the May-Bloom Tea Plantations, Limited, which appears in several papers. It is evidence of the keen competition in the tea trade and the necessity for novelty of idea, if of nothing else. The company, in its prospectus, appeals to the grocer to take shares, and thus "become" his own planter, and he will then (assisted by powerful advertisements) "be in a position to successfully contend against the severe competition arising from firms who style themselves 'planters,' or who, by weight of their advertisements, threaten to monopolise the sale of one of the most profitable articles of the retail dealer." The

proprietary rights are offered to only one grocer in a district, and can be acquired by the purchase of one or more proprietors' shares of £10 each, bearing a preferential minimum dividend of 5 per cent., the holding of which confers the following advantages:—“The teas from the plantations acquired by the company will be packed in the usual way in chests, half-chests, and boxes, and will be offered on arrival direct to the proprietors, thus doing away with the intervention of middlemen, and giving the proprietors an opportunity to buy at prices considerably under those usually charged by the London wholesale dealers. Samples will be submitted in reply to enquire, and it will be quite optional for a proprietor to purchase or not. By this means his method of buying, or his existing style and uniformity of blends, will not in any way be disturbed. Each proprietor will thus be in a position to state that he supplies teas direct from his own plantations, of which views and full particulars can be obtained for exhibition on his premises, as well as forcible handbills, &c.; these, with well-directed advertisements, as stated hereunder, will form a very powerful medium to attract fresh customers. The following arrangements, the prospectus states, “have been entered into with the Planters’ Stores and Agency Company, Limited, of 1, Great Winchester Street, London, E.O., who are largely interested in tea planting:—1. The Planters’ Stores and Agency Company Limited, undertake to pay to the company, for the benefit of the holders of proprietors’ shares, an aggregate sum equaling 5 per cent on the amount of such shares for the time being issued, to be distributed amongst the holders as remuneration for their services as resident agents for the sale of May-Bloom Tea, subject to such payment ceasing when the profits of the company suffice to pay the full amount of the preferential dividend. 2. To manage the plantations and entire work of the company at a moderate remuneration. 3. To advertise in conjunction with the grocers’ names in the country Press, by hoard at railway stations, and various other ways. 4. To confine the sale of the now well known brand, ‘May-Bloom Tea,’ exclusively to the proprietors in their respective districts. 5. To offer to the proprietors at specially-reduced rates their well-selected stock of original teas from India, Ceylon, &c., standard blends and other packets held at their ‘May-Bloom Tea’ depot at 32, Middlesex Street Abchurch Lane.”

THE INVESTOR WARNED OFF.—We notice that an evening paper, *The Echo*, refers to the above concern [Ceylon and Oriental Estates Co., Ltd.] as “A Baring Relief Company,” and it says:—“How is it, for instance, that no names of old Ceylon planters are given as applying for shares? If the opportunity of acquiring these estates is so exceptional, how is it that a large proportion of the capital required has not been subscribed by rich proprietors and retired planters, of whom there are scores in London? Let the directors proclaim that in answer to a prospectus posted up in the room of the ‘Ceylon Association in London’ some two or three thousand shares have been taken by Ceylon men, and we shall unhesitatingly advise the public even to pay a good premium for the remainder of the shares. Less than a month ago Mr. Ferguson addressed a room-full of Ceylon residents, active and retired, at the Royal Colonial Institute; how many of these are assisting to relieve the Barings and Mr. Thring of their Ceylon estates at a valuation based upon the profits of 1891, when tea averaged a fair higher price? We venture to say, not many. Nor are the estates themselves by any means the pick of Ceylon properties. On Peacock Hill and Bogahawattie the wind is damaging, both occupying exposed situations. The former is situated just below the Upper Peak estate of Mooneragalla Mountain, and the latter at the Gap (Bogahawattie Gap), between Dimbula and Kotmale. For obvious reasons, it would be fatal to sell any additional jungle land, if by so doing it gave access to the violent wind prevalent during two months of the year. Be all this as it may, however, the fall in the price of tea, and its entire omission from the prospectus, is quite sufficient warranty for us to recommend prudent people to leave the Ceylon and Oriental Estates Company to those persons who are well ac-

quainted with the estates, and also with the rational forecasts made of the tea market by brokers and dealers.”

THE BI-METALLIC QUESTION.—A numerously attended meeting of bankers and merchants was held on Tuesday night in the Board room of the New Oriental Bank, London, to consider the position of the currency question, with special reference to the interests of the City of London. Mr. J. Howard Gwyther occupied the chair. After some discussion the following resolution was unanimously passed:—“That a City of London Committee of the Bi-metallic League be formed to urge upon the British Government the necessity of co-operating with other leading nations for the establishment by international agreement of the unrestricted coinage of gold and silver, at such fixed ratio as may be agreed upon, and that the following gentlemen constitute such Committee, with power to add to their number:—H. H. Gibbs, M.P., Sir Thomas Sutherland, M.P., S. Montague, M.P., A. D. Provand, M.P., Sampson S. Lloyd, H. R. Grenfell, Sir Hector M. Hay, J. Howard Gwyther, Edward Sassoon, Renben Sassoon, Edward Langley, J. T. Horley, A. Von Andre, H. R. Beeton, David McLeau, H. Schmidt, J. F. Ogilvy, Herbert C. Gibbs, Thomas A. Welton, Henry Coke, R. T. Rhode, A. Zimmerman, A. Cottrell Tupp, W. Koswick, and W. Paterson.” It was also decided to hold a public meeting at the City of London Institute on Saturday Evening, at which Mr. S. S. Lloyd has consented to take the chair, when Mr. H. C. Gibbs will read a paper on silver question in relation to the interests of the City of London.—*H. and C. Mail*, April 8th.

AVERAGE PRODUCT OF FRUIT TREES.—To those who desire to estimate the crops of the future, the following table will be of some interest. It is based upon a fair average production of trees in full bearing and under proper treatment, planted as usually in orchard:—

	TONS PER ACRE	TONS PER ACRE
Apples.....	4	Walnuts..... 1½
Apricots.....	5	Almonds..... 14
Pines.....	6	
Pears.....	5	BOXES PER TREE.
Figs.....	8	Oranges, budded... 6
Peaches.....	5	Oranges, seedling 12
		Lemons, budded... 5

—*Rural Californian*.

COFFEE CULTIVATION IN JAVA.—A report from the British Minister at the Hague on Netherlands-India describes the connexion of the Government with coffee cultivation in these colonies. The greater number of the coffee plantations in the Dutch possessions are directly under Government management, the natives being compelled to cultivate coffee in place of paying taxes, while the authorities receive the whole of the produce at the fixed price of 15 florins (£1 5s) for every picul of 133 1-3rd lb. A certain amount is then disposed of in the colonies themselves, and the remainder is sold in Amsterdam and Rotterdam, the usual practice being not to sell one year's crop in Holland until the following year, although, as an exception, part of last year's crop was sold towards the close of the year. The fluctuations in the returns from coffee have of late years been considerable, owing mainly to variations in the yield. But it also appears that a change has come over the conditions of cultivation in consequence of the exhaustion of the soil, which has had the effect of compelling the Government to handon it to some districts. The labour on the plantations is not now the only form of taxation to which the natives in Netherlands-India are liable. Formerly feudal service, in the form of so many days' labour, was enacted, not only for public works, but for the private benefit of native officials. In 1822 these services, so far as the native officials were concerned, were abolished, occupation being made to them in the shape of an increase of salary, while a poll-tax of one florin was imposed on the natives. The amount of this tax was found to be more than was required for the increase in salaries, so that the authorities have been enabled to abolish all compulsory services, the surplus yielded by the tax defraying the expenses consequent on the abolition.—*London Times*, April 16th.

MR. JOSEPH HATTON'S ARTICLE ON "COCOA" IN THE "ENGLISH ILLUSTRATED MAGAZINE."

The article which we quote (see page 912) is interesting not from any special knowledge which Mr. Hatton possesses of *Theobroma cacao* and its culture as from the graphic description he gives of the gigantic works and the multitudinous machinery by which the seeds are manufactured into various preparations at the Messrs. Fry's extensive works in Bristol. Mr. Hatton indeed quotes a so-called "technical authority" as writing "Coca leaf, cocoa-nut, cocoa; it requires thought before one can rightly attribute the properties and uses of these vegetable products." We should think so, since there is no such vegetable product in commerce or the pharmacopoeia as cocoa leaves: indeed cocoa itself is a most unfortunate corruption of cacao. What the "technical authority" misnamed "cocoa leaves" are the leaves of *Erythroxylon coca*, which the Peruvians chew as a stimulant, and which has been recently found to yield a most valuable anæsthetic. Neither is there any vegetable production in existence, which is properly named "cocoa-nut." The fruit of *Cocos nucifera* is properly coco-nut, and the tree on which it grows is the coconut palm. The grand old lexicographer, Dr. Johnson, knew this, and he described the palm by its proper name. The confusion arose from the mixing up by the printers of the definitions of coconut and *Theobroma cacao*. Let us recapitulate the three strictly correct names, to the orthography of which all intelligent writers ought to adhere:—

Coca leaves.

Coco nuts and palm.

Cacao seeds, nibs, Fry's, &c.

"Cocoa" is absolutely inadmissible; and yet a practised literary man, like Mr. Hatton, not only quotes the "technical authority" as we have shown, but himself writes:—"Many think *cocoa* nibs are made from a root, others associate them with the *cocoa*-nut palm." And then he mentions an established dictionary in which an engraving of a "*cocoa*-nut" palm is used to illustrate the word "*cocoa*." The leaves of *Theobroma cacao* may in shape resemble those of a plum tree, but they are really gigantic leaves, such as no plum tree ever wore. We should say that "100 nuts or more" in a cacao pod was a rare occurrence, 25 to 50 being a more common average. But, as we have said, the interest of the article centres in the complicated and numerous manufacturing operations described, and here Mr. Hatton is at home describing what he actually saw. Cacao differs essentially from coffee and still more from tea in requiring so much preparation before it can be used as a beverage, or a confection. All that is necessary in the case of coffee beans is that they should be roasted, ground, and treated with hot water, while the dried tea leaves require simply to be infused in boiling water poured over them and allowed to remain not more than five minutes. As to cacao it is positively bewildering to read of the processes to which the beans or nuts are subjected by means of machines fully illustrated in the article we are noticing. Amongst other machines there are hydraulic presses of great power, some of which are used to express the oil which exists abundantly in the cacao beans. The coffee bean and the tea leaves have each a subtle essential oil on which their flavour depends, but we never heard of coffee beans yielding a fatty oil, and in the case of the tea plant such an oil is yielded only by the seeds. We have never heard that this oil was of any economic value, like cacao butter; Cacao,

in truth, is a food (*theobroma*, food of the gods): while tea and coffee, although by no means wanting in nutritive properties, are more specially valuable as cheering and restorative stimulants, without producing any of the reaction which accompanies the use of alcohol. The first illustration is an engraving from a drawing taken in Ceylon of a portion of a cacao plantation with four characteristic Tamil women opening the pods and dropping the seeds into baskets. Then we have:—A corner of the roasting room; grinding pure chocolate; a pug mill or mixing pan; rolling sweet chocolate; hydraulic presses for extracting "*cocoa*" butter from concentrated "*cocoa*"; stirring the sugar cream; filling packets of "*cocoa*"; and finally packing fancy chocolate. In the two last women only are represented, many of whom find employment on the works, connected with which altogether, when a new factory is completed, there will be very nearly 3,000 men, women and children. For the physical as well as the physical and intellectual well being of their people the Messrs. Fry have conscientiously provided. It seems that a bad roast would be as fatal to cacao as a bad wither would be for tea, and granite rollers are used for grinding, as iron would set up injurious chemical action. It will be seen that immense quantities of refined sugar are used in the manufacture, and that the Messrs. Fry make most of the machinery they use, manufacturing also wooden, tin and paper boxes &c. It will be noticed that artificial cold is essential to some of the processes. But for details of great interest, on which we cannot touch, we must refer our readers to the article we quote. Before we read it, we had no idea of the large measure of employment afforded by the manufacture in Britain of the twenty-one millions of pounds of cacao seeds on which duty was paid in 1891. From the points of view of home employment and the elegance and delicacy of the articles turned out,—some of them, orange flavoured,—cacao certainly excels either tea or coffee. Our staple has the great merit, however, of reaching the Home market and the consumer perfectly ready for conversion into

"The cups which cheer but not inebriate,"

which is really the form in which Cowper described tea. It is something for this colony to boast that her coffee, her tea and her cacao have been amongst the best the world has produced. As to the cacao, there is certainly no question.

In Ceylon we produce a small quantity of high quality *coca* leaves; a considerable quantity of highest quality *cacao*; and many millions of excellent *coco*-nut.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, April 7th.

CINCHONA.—The fortnightly auctions held on Tuesday were of small extent, the catalogues comprising of

	Packages	Packages
Ceylon bark	611	of which 577 were sold
East Indian bark	1,128	do 1,110 do
Java bark	6	do 6 do
South American bark...	249	do 118 do

Total ... 1,994 do 1,811 do
The assortment was a good one, and included a large quantity of Indian Officialis bark, both original and renewed, and several very good lots of red and yellow bark. The sales were very irregular, competition being almost confined to two firms. Ordinary qualities were generally lower, but for rich barks full prices were paid. The average unit remained 1½ per lb.

The following are the quantities bought by the principal buyers:—

	Lb.
Agents for the American and Italian works	142,175
Agents for the Mannheim and Amsterdam works	124,545
Agents for the Frankfurt o/M and Stuttgart works	88,860
Agents for the Brunswick works	35,112
Agents for the Auerbach works	40,778
Messrs. Howard & Sons	34,203
Sundry druggists	28,250
Total quantity of bark sold	461,943
Bought in or withdrawn	44,820

Total quantity of bark offered ... 506,763
ESSENTIAL OILS—Small sales of Citronella oil are reported at 4d, and of Lemongra-s oil at 1 9-16ths d. per oz on the pot.

THE EXPORT TRADE OF CHINA FOR 1891.

was the highest in value ever known, even tea showing a large increase over the previous year. Curiously enough India takes an appreciable quantity of China green tea. We quote as follows from the *China Mail*:—

The total value of exports abroad for the year aggregated Hk. Tls. 100,947,000, which is the highest point ever reached, and shows an advance over the figures of 1890 of Hk. Tls. 13,800,000. The majority of products enumerated in the table of exports on page 10 compare very favourably with the shipments of the previous year; but the three great staples—tea, silk and cotton—contributed most to the increase in the total given above. In value and quantity the gain in favour of 1891 yielded by teas of all sorts was Hk. Tls. 4,365,000. White and yellow silk added Hk. Tls. 5,928,000, with 24,574 piculs over the export given in last year's returns, and silk piece goods, Hk. Tls. 1,143,000, representing 2,028 piculs above the total of the previous twelvemonth; while raw cotton, with an increased export to Japan of 56 698 piculs over 1890, added Hk. Tls. 852,000. Wool, camels' and sheep's, from the northern ports exceeded the shipments of 1890 by 36,625 piculs, estimated at Hk. Tls. 258,000. The other articles, which should be noted as showing conspicuous gains over previous statistics, are paper for Chinese consumption abroad, camphor from Formosa, matting from Canton, and musk—each of these exports contributing more than Hk. Tl. 170,000 over the figures of the previous year to the total for 1891.

The shipments of raw silk were: white and yellow silk, 84,948 piculs; wild silk, 17,043 piculs; and refuse silk, 60,703 piculs—these amounts being much over those of 1890, a low rate of exchange favouring the consumption of Chinese silks in Europe.

The export of tea of all kinds, including the shipments from Kowloon and Lappa to Hongkong and Macao, amounted to 1,750,034 piculs, showing an advance of 84,638 piculs over the total for 1890. From Kowloon and Lappa the export of black tea in junks to Hongkong and Macao is more than double that of the previous year, the large increase being ascribed to a reduction in the provincial duty on that article when shipped by junks. The addition of this junk-borne tea to the total quantity sent abroad in foreign vessels raises the export to more than the shipments of 1890, and for the time being has arrested the decline which characterised the black tea trade of recent years, the excess in favour of this year being 52,565 piculs above the crop of 1890, which is returned at 1,149,311 piculs. Green tea also shows an improvement of 7,256 piculs, and brick tea for Russian account 31,693 piculs. Russia appears to be the only large market in Europe where the demand for China black tea is maintained. Supplies continue to be sent by sea in increasing quantities, shipments having risen from 93,467 piculs in 1887 to 189,025 piculs, or double the quantity; and while the consignments by sea and land to Russia in 1887 aggregated 267,000 piculs, they now amount to 287,000 piculs, representing a gain of over 20,000 piculs. It is worthy of note that the demand for China tea (chiefly green) from India has doubled within the last five years—13,917 piculs being credited to the Empire in 1886, against 30,319 piculs during the year under notice.

From the *North-China Herald* we take the figures for tea exports, with comments on the still great tea trade of China:—

	1891.	1890.
	Hk. Tls.	Hk. Tls.
Tea Black.....	24,979,259	20,579,818
„ Green.....	3,545,911	3,700,488
„ Brick.....	2,328,755	2,136,720

The three great staples, tea, silk, and cotton, gave, it will be seen, the highest increases, Japan being the most eager customer for cotton; the large increase in silk is to be attributed to a great extent to the lowness of exchange; but the large increase in the value of the black tea exported will come as a surprise to many. Judging by the falling-off in the demand for China tea in England we have come to think of the whole China trade in tea as a declining one; but fortunately for China she has one customer, Russia, that has not yet been affected by the craze for Indian and Ceylon teas, and thus the export for 1891—although none of the numerous suggestions that foreigners have made for the rehabilitation of the trade have been put into practice—from all China shows an actual advance of pls. 52,565 over that in 1890. Green tea also shows an improvement of pls. 7,256, and brick tea for Russian account pls. 31,693. The proportion of tea sent to Russia by steamer via Odessa continues to increase rapidly, for while only pls. 93,500 were sent by that route in 1887, rather more than double that quantity took that route in 1891. Of the large consumers of tea we find that the principal were in 1891:—

Russia, Siberia, and Russian Manchuria.....	Pls. 636,000
Great Britain, Hongkong, and India.....	„ 540,000
United States.....	„ 276,000
Australia and New Zealand.....	„ 106,000

In the Russian figures are included some pls. 330,000 of brick and tablet tea; but they do not include some pls. 50,000, which are sent from Hankow up the Han river for overland carriage to Siberia. The total export to foreign countries of pls. 1,750,034 in 1891 has to be compared with pls. 2,217,295 in 1886, the largest in the past ten years.

THE ALLEGED QUININE SYNDICATE.

We have received the following from Germany, dated, by the way, April 1:—“A project has been formed by London importers to establish, in conjunction with the Amsterdam importers, a ring for the maintenance of the price of quinine. The capital to be invested in this object is 300,000 florins (25,000*l.*). The representative of a large London firm has been staying in Amsterdam since the beginning of this week to bring the project to a conclusion. If he succeeds in his object the quinine-makers might easily be forced, through the reticence of the bark-holders, to ask for quinine a price very much in excess of the present one. It is reported from America, by certain persons well acquainted with the market, that some German quinine-makers have sold large quantities of quinine (1,500,000 oz.) for future delivery at from 17½ to 18½ cents, c.i.f. New York. Such sales would prevent any substantial increase in the price of quinine, as quantities of such magnitude placed upon the market at regular intervals would provide second-hand holders with an abundance of cheap material.”

THE AMSTERDAM VIEW OF IT.

We have made inquiries from some of the best-informed persons in Amsterdam concerning the truth of the report above alluded to, and are told that it is believed to be a fact that a London gentleman interested in cinchona has tried to persuade the chief importers in Holland to consent to the formation of a combination, to embrace planters in Java, Ceylon, and British India, for the object of strengthening the bark market. It is not denied that “something like a meeting” may have been held with this object just before the last Amsterdam bark sales, and that this meeting may have had something to do with the

firmness of certain importers, which led to the buying-in of about one-third of the bark catalogued. But, notwithstanding all this, the representatives of the Java planters in Holland, without it is believed, a single exception, are convinced that if the Java growers were now to ally themselves with those of Ceylon, they would in the words of the first Napoleon—"s'allier à un cadavre"—bind themselves to a corpse, and commit a fatal blunder. An Anglo-Dutch syndicate therefore, seems to be out of the question. If any combination is formed in Amsterdam it will consist on Java planters only.—*Chemist and Druggist*, April 9.

FOOD OF THE GODS.

How to make a perfect cup of chocolate, is an art not mastered in many households. A cup of chocolate as served by Menier or Maillard, is a very different thing from a cup prepared by Bridgot, in the early hours of the morning and served to one who must hasten for the morning train. The Directeur of the American branch of Chocolat-Menier, of which over 30,000,000 pounds are consumed annually, gives the following directions for preparing Menier Chocolate as a beverage: "For each cup desired, break into small pieces one-half of the six divisions into which every half pound package is divided. Place in a saucepan and add sufficient boiling water to reduce the chocolate to a smooth paste by stirring it constantly with a wooden spoon over a brisk fire. When thoroughly dissolved add a cup of unboiled milk, either cold or warm, and boil for about four minutes, stirring it frequently. Serve while hot and you will have a perfect cup of chocolate."—*American Grocer*.

CEYLON TEA PLANTATIONS COMPANY, (LIMITED)

Report of the Directors to be submitted at the fifth annual general meeting of Shareholders to be held at Winchester House, Old Broad Street, E.C., on Friday, 20th April, 1891, at 2.30 p.m.
The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 31st December, 1891, duly audited.

The net amount at credit of Profit and Loss Account, including Balance brought forward at 31st December 1890, and after providing for General Expenses, Directors' Fees, Income Tax, &c., is	31,439	3	3
An interim dividend of 7 per cent. on the Ordinary Shares was paid 27th October, 1891	10,254	6	0
It is proposed to pay a final dividend of 8 per cent. on the Ordinary Shares (making 15 per cent. in all, free of Income Tax) which will absorb	11,727	4	0
A Dividend on the 7 per cent. Preference Shares was paid on 30th June, 1891	1,018	3	11
A Dividend on the 7 per cent. Preference Shares was paid on 31st December, 1891	1,732	13	2
It is proposed to add to Reserve Fund	5,498	8	0
And to carry forward to next year a balance of	1,213	8	2
	31,439	3	3

The Directors are pleased to be in a position for the fifth consecutive year to recommend a total dividend of Fifteen per cent. on the Ordinary Shares. It is proposed to place £5,498 8s 6d to the Reserve Account, making that Fund up to £20,000, and to carry forward £1,213 8s 2d to next year.
The gross average price realized for the Company's Teas, sold in London, was 9½d per lb., this being

1½d per lb. under that of 1890, but the net cost of production was ½d per lb. less than that of previous year.

There were 5,090 acres from which leaf was plucked, and this area yield 414 lb. per acre, the crop being as under:—

Tea from Company's Estates.	Bought Leaf Tea.	Tea manufactured for others.	Total.
lb.	lb.	lb.	lb.
2,088,291	886,565	1,318,735	4,291,591

The Company's properties consist of the following:—

Descriptions.	Acres.	Total.
Tea in bearing ...	2,300	5,393
„ not in bearing ...	2,345	2,546
„ seed ...	27	27
„ to be planted 1892 ...	82	82
Office ...	60	60
Jungle and timber clearings ...	1,789	1,789
Patena and waste land ...	363	397
Totals ...	9,656	10,294

It is gratifying to the Directors to be able to assure the Shareholders that the Company's properties are in excellent condition. The Factory accommodation and machinery, which were scarcely equal to our requirements during the past year, are now being increased to meet the largely-expanded business of the Company.

The Directors have again to record their high appreciation of the services rendered by the various Officers of the Company in Ceylon and London.

Mr. G. A. Talbot, the Company's Manager in Ceylon, having been granted leave, it is proposed that he be appointed a Director during his stay in England in the place of Mr. Henry Tod, who has resigned his seat on the Board.

Mr. R. H. Miller, of Messrs. Harper Bros., Auditor, retires from office, but offers himself for re-election.

DAVID REID, Chairman.

London, 14th April 1892.

WHAT DR. LEMON WILL DO?

Do you want to know the name of one of the best all around household doctors, and certainly the cheapest that can be found in any country?

It is Dr. Lemon. Yes, an ordinary, sour, yellow lemon, which you can buy at any grocery for a few cents.

Here are some of the things Dr. Lemon will do for you if you give him a chance,

Squeeze him into a glass of water every morning and drink him with very little sugar. He will keep your stomach in the best of order and never let Mr. Dyspepsia, whom he hates cordially, get into it.

If you have dark hair and it seems to be falling out, cut off a slice of the doctor and rub him on your scalp. He will stop that little trouble promptly.

Squeeze him into a quart of milk and he will give you a mixture to rub on your face night and morning and get a complexion like a princess.

Pour him into an equal quantity of glycerine and rub your hands with the mixture before going to bed. If you don't mind sleeping with gloves on that is better still and helps the doctor considerably in his task of whitening your hands. In the morning wash your hands thoroughly in warm water and apply the doctor again pure, but only a few drops of him this time. You must not keep this up too long or your hands will show such a dazzling whiteness as to make all the other young ladies in the vicinity jealous.

If you have a bad headache cut Dr. Lemon into slices and rub these along your temples. The pain will not be long disappearing—or at least in growing easier to bear.

If a bee or an insect stings you clap a few drops of the doctor on to the spot and you will find yourself he better for it.

If you have a troublesome corn the doctor can be again put to good account by rubbing him on the toe after you have taken a hot bath, and cut away as much as possible of the troublesome intruder.

Besides all this the doctor is always ready to sacrifice himself in the cause of Russian tea—slice him in without sugar—or in the preparation of old-fashioned lemonade, than which no drink is more wholesome.

Altogether Dr. Lemon is an individual few people can afford to get along without.—*Exchange.*

PLANTING IN THE NEW HEBRIDES.

From a letter dated to a gentleman in Colombo, we quote as follows.—

"Santo, New Hebrides, Feb. 10th, 1892.

"Just a line to let you know that we are applying to Japan for coolies, and as far as we can see at present, any number can be had for the cost of transport and about sixpence per diem for their work.

"It may not have struck you that in these islands a man has advantages that cannot be formed elsewhere.

"No restrictions with regard to imported labour which he can get from China, Japan, Malay or anywhere at his own price and on his own terms.

"If a few planters came out we could send our own chartered vessels and bring as many labourers as we require, and as to the question of titles to the land, that would be perfectly secure as we could get the islands annexed without trouble if settlers were here, and you have time to make a fortune or lay the foundation of one before there are too many laws or restrictions. Sugar planters could send the labour vessels up to Japan and load up thousands and there is nothing to prevent going to work at once. This end of Santo, Malo and Mellicolla has good low land for sugar and the natives as you are aware are anxious to sell for what they can get.

"We have been pushing the authorities for annexation, and no doubt shall get it in time, but it is questionable whether we should not be acting more to our advantage if we sent a vessel up to Japan for 200 coolies.

"We are getting islanders now by the mail steamer under the same laws that enable the mission stations to obtain native cooks and teachers from other islands.

"We pay their passages by steamer and the expense is less than in any part of the world, £3 per head and no restrictions. I think we can get them from Japan under £5 per head. What more do the planters want? There is no drought here to burn up the cane fields, and no heavy timber to clear.

"Price of land about one penny per acre cash or 100 acres for a market and you would never be troubled by seeing a native unless you encourage them and come to trade or work."

COCOA.

By JOSEPH HATTON.

(Illustrated by W. H. Margeson.)

"Cocoa-leaf, coco-nut, cocoa," remarks a technical authority, "it requires thought before one can rightly attribute the properties and uses of these vegetable products." Many persons think cocoa-nibs are made from a root, others associate them with the coco-nut palm. I could hardly realize the existence of so much ignorance or indifference about one of the most familiar of popular beverages and confections until I opened an established dictionary and found an engraving of the coco-nut palm illustrating the word "cocoa." The great Encyclopaedia do not however leave one in doubt. Cocoa is the product of the seeds of the *Theobroma* (Food of the Gods) *cacao*. The tree flourishes in Mexico, Brazil, the West India Islands, Columbia, Ecuador. The finest qualities are grown in the island of Trinidad, and in Venezuela. Caracas has given its name to a popular brand. Of late years, Ceylon also has produced a bean of high character. A drawing made in a

leafy corner of that sunny island supplies us with our initial illustration. The *Theobroma cacao*, better known as the cocoa tree, rises with a bare stem to the height of six or seven feet, and then dividing into many branches climbs upwards some ten or fifteen feet higher. The branches spread out not unlike an oak, but with a dark green leaf something of the shape and character of a plum tree. The fruit is a large pod that hangs pendulous from the tree by a tough timber stalk. Its surface is grained and hard. At first the pods are green, but as they ripen they become yellow, the side next the sun red. The tree attains its full vigour in seven or eight years, and yields two principal crops in the year. There is not what may be called a harvest time, not in the sense of our cutting of corn or the vintage in France. The pods do not ripen all at the same time. One or two from a tree are sent as they appear to the eye of the expert as ready for stripping. These are gathered together in heaps, and by and by the plantation hands, men and women, burst open the pods, strip away the rind and extract the nuts, each pod containing a hundred or more packed in the closest compass. The nuts are then laid out upon mats to dry, after which they are packed for exportation in bags, each of which holds about 112 lb.

Recently, in company with a friend, I saw vast quantities of the luscious-looking bean turned out of its Oriental packing in "the cocoa metropolis" of the West of England, and watched its gradual conversion into that particular "food of the gods" which has become universal among men. Bags from Trinidad, Venezuela, Ceylon and other cocoa regions were being swung through the air into the storage and grinding room of Fry's factories at Bristol. Panning in one of the galleries that unite the different factories to watch the busy scene below us, we find ourselves on a level with the vane of St. Bartholomew's Church steeple. The sacred edifice is literally imbedded in the secular buildings that have grown up all round it. The children pouring out of the church-schools might be part of the working-folk of the factory going to dinner. They all look free and happy and well nurtured, the working children as well as the scholars with their books and slates. St. Bartholomew's is one of those out-of-the-way churches which you often find in old cities lost in the noisy thoroughfares of growing industries, their congregations dispersed among other houses of prayer. A new site will evidently have to be found for St. Bartholomew's. From the first it would seem as if trade and commerce had been struggling at Bristol for supremacy with ecclesiasticism. In the fifteenth century it was "a city of towers," eighty monasteries and churches crowning its embraided walls. Prior to the edicts of Henry VIII., it was indeed more or less an ecclesiastical city, crowded with devotional guilds, hospitals, hermitages, churches, chantries, the population picturesque with the typical costumes of Franciscan, Benedictine, Carmelite and Dominican monks, priests, and friars, the air (says one historian) "thick with clouds of incense." If the possible conversion of the site of St. Bartholomew's into business purposes should strike a note of regret in some minds we would hasten to offer the compensating fact of the annexation of the county gaol for the firm's stables and timber stores. Indeed the exigencies of cocoa manufacture seems to have compelled a general making free with the western city. Fry's brassplate meets the eye in the various business quarters of the city, setting up fresh landmarks for old ones, and filling the air with a perfume at some points hardly less noticeable than was the incense of Bristol's olden days.

We had paused at the open door of the roasting room, not only to witness the unloading of tropical cargoes hut to take a glance over the red-tiled roofs and gabled houses of Bristol away to St. Paul's in Portland Square, busy streets right and left and at all points, suggestions of the historic character of the famous old city and its merchant venturers, its battles for king and parliament, its royal and civil banquetings, its reform riots, its literary eeteries, and its varied enterprises maritime and otherwise.

A fine old city Bristol, full of ancient landmarks, rich in architectural treasures, a vein of romance and poetry running right through its history from the days when Cabot sailed out of its picturesque port to discover new worlds to the present time when ships from every sea float upon her lazy tides and moor themselves in the very heart of the city as they do to this day in Amsterdam and Yarmouth. But our courtesa guide awaits us and we must postpone for the time being such wayside reflection as do not come within the immediate focus of our work. The bags already mentioned are upon this floor, emptied into several roasters, cylindrical pans slowly revolving over open coke fires. The bean is stirred now and then by experienced attendants who can tell by the flavour of the vapour that arises from them when the operation is complete. This first process is the most important of the series of treatments which the cocoa bean undergoes before it is ready for the breakfast or dessert table. A bad roast is fatal. The bean is destroyed. But a bad roast is a very exceptional incident. From the roasters the beans are conveyed to large hoppers connected with the floors beneath by shoots that convey the roasted bean to the winnowing room. Here a machine cracks the nut, removing its hard outer skin or shell, and both are together hauled to a point over the winnower where the blowers separate the husk from the nut, and the latter now being thoroughly cleaned from all *débris* of the shell becomes what we know as cocoa-nibs which are now ready for grinding.

As there are four main factories, each more or less reproductions of the other, the various departments are known in the works by numbers, but for the better understanding of the reader we prefer to give them proper names. Thus from the grinding room we come to the sugar-grinding room, which is incidental as it were to the next operation which belongs both to the manufacture of chocolate and the ordinary drinking cocoa. We might now be in one of the floors of a flour-mill, so white is the atmosphere, so ghost-like the workpeople. Tons of loaf-sugar are here ground and sifted until it is as fine as the finest flour, and as soft and silky to the touch. As the salt-sea waves leave their flavour upon the lips, so does the flying dust of the sugar-room leave behind its sweet if not cloying flavour; and one also leaves the room as to beard a trifle grayer than one entered it. This little world of "sweetness and white" gives upon the pan or pug-mill room, where the cocoa-nibs, in great revolving pans, are mixed with the fine-dressed sugar and pounded between granite rollers into paste. No water is used, but the material is kept warm. There is a large percentage of oil in cocoa-nibs, and encouraged by a gentle heat it is brought forth, and thus the nut or bean becomes liquified. Sugar is added until the cocoa is of the consistency of dough. The heads of the revolving pans are of granite like the rollers. Iron would set up a chemical condition inimical to the delicate flavour of the product. When the nibs find their way into these heated mills they are hard and brittle, and one might expect to see them ground into powder. Not so; they become paste as we have seen, and in this form are made to perform all kinds of strange evolutions. It is whirled hither and thither in the great pans, making graceful curves, now ejected in liquid columns like miniature Severn "bores" or enormous snakes, rich brown tortuous never-ending boa constrictors; thence it goes into batteries of rollers where it is conducted over granite cylinders, flattened out and rolled by a series of ingenious machines invented and made in Paris, and comes out chocolate, except that it has to cool. This hardens the oil of the nib, called "cocoa butter," and the chocolate is then ready to be prepared for use.

Skipping the floor we have just described a certain proportion of the ground nibs come to the department to which we next descend, falling into hoppers that make the powder finer and finer. For storage purposes there is a curious little machine here, originally made for pressing patent fuel into blocks. Later the inventor applied it to cocoa in this way. The

material is placed in an automatic metal box, the lid is closed, then by pressure the bottom is forced upwards until the lid opens to let out the compressed brick of cocoa which is then stored. Passing this little machine we are in one of the most picturesque departments of the factory. There is no more artistic form than that of a wheel, nothing in continual motion that gives a greater idea of power. The avenging Jupiter could think of no punishment so persistent as that of the whirling wheel to which Mercury bound the banished Ixion. In every manufactory the wheel is familiar enough. It is the motor of the place, the guide and controller of miles of straps and bands; it is beginning and never-ending in almost every nook and corner; but we have rarely seen it in such striking evidence as in one particular department of these great cocoa factories. Here on this floor of hoppers into which the ground nibs are deposited to make concentrated cocoa the sense is bewildered, the mind fascinated, by the incessant repetition of wheels. They fill the ceilings in two or three vast circles, that have their revolving satellites like moons each on its own axis, and each governed by the master wheels. The curious part of the scene for a novice is literally a ceiling of moving wheels as well as a continuation of the same right, left, and centre. Watch them for any length of time and you might find yourself presently going round and round with them until you whirled yourself out of existence like the grating maiden in the fairy-tale. To the turn of these many wheels the mills perform their eccentric motion until the chocolate is sufficiently ground. It is then collected in batches and placed in canvas bags, which are packed into the receivers of a long array of hydraulic presses that also constitute a very interesting scene. At first blush you might think you had strayed into the counting-house of the firm of Gogs and Magog whose letter-copying presses stopped the way; but these double-handed machines are worked by a power greater than that of a thousand Gogs and Magogs with an army of Polyphemuses thrown in. The canvas bags subjected to hydraulic pressure give forth most of the oil which the cocoa contains. It runs off into tin pans and leaves behind the dry pure cocoa of commerce. The oil is of a dark brown colour, but as it cools it gradually becomes white and in solid blocks. Later we come upon it turned out of the tins "cocoa butter" in great solid pats. On this and other floors there are large artificial cooling rooms, for which there is on the ground floor extensive frost-generating machinery on the brine and ammonia system. The shafts go up through the various factories as do also the lifts or elevators. Even in summer days the artificial snow has to be collected and removed from the freezing closets.

Passing through the rooms devoted to the mixing of miscellaneous chocolates we now leave what may be called the manufacturing departments. We have not thought it necessary to mention the separate treatment of different varieties of bean, Trinidad, Caracas, Ceylon, and others. The process does not vary. In quitting the grinding, winnowing, milling, pressing and other operations we leave behind us the men's work. Not that the master hands do not appear in the lighter sections of the factories, but girls and women predominate in the later departments which belong to the production of chocolate creams and fancy confections. On our way to the ground floors we come upon one of the rooms set apart for the filling of cocoa tins and packets. Here crowds of girls are weighing and packing the brown powder. They are a healthy, well-dressed company of young women, and of a more than ordinary look of intelligence. The ground floor of the factory is devoted to many varied purposes. First, we come upon the busy scene of sugar boiling, long rows of boilers, long rows of men in white French caps and aprons. From the boilers the sugar is emptied upon great stone slabs where a little army of more white-capped labourers stir and beat up the cream-like compound with white wooden spades. Thus prepared it is transferred to the moulds; and this brings us to another department that repeats the atmosphere of the sugar mill. Moulds for iron castings, as you are aware, are made of sand,

The creamy sugar which we have seen boiled and manipulated for the next process is poured into moulds made of starch. We find ourselves in the midst of stacks upon stacks of these square moulds, flanked by bench after bench of men and boy moulders. Wherever labour is divided by machinery or hand, one operation dependent upon another, there is no time for idleness. The machine, human or otherwise, must be kept going. Here moulds are filled and emptied with a steady and effective monotony. On one side the sugar cream is poured into the moulds from handy funnels; on the other, when solidified, resultant creams are collected for ultimate coating with chocolate. Leaving the moulding rooms we seem to drift to and fro into various other departments where thousands of trained dainty fingers are giving the finishing touches to fancy forms of creams and plain chocolates that gradually develop into all kinds of boxes, from the cheap popular little *bombon* boxes to the handsome and artistically arrayed and decorated cabinet of mixed sweets fit for the notice of a Princess.

And now once more in the fresh air we make the acquaintance of the engines and boilers all on the most perfect scale, even to the oldest mechanical servant of the firm, a great old beam engine of the melancholy mad-elephant kind described by Dickens. It has been in use over fifty years, and in its present site was erected the first engine that Boulton and Watt introduced to Bristol. The old-fashioned but powerful engine has been supplemented by many others. It takes eight powerful sets to drive the works in these days. They would be a surprise to the writer of a paragraph in the *Bury and Norwich Post*, of June 6, 1798, could he once more visit the glimpses of the moon. "Since the great improvement of the steam engine," he wrote on that particular date, "it is astonishing to what a variety of manufactures this useful machine has been applied; yet it does not a little excite our surprise that one is used for the trifling object of grinding chocolate; it is, however, a fact, or at least we are credibly informed, that Mr. Fry of Bristol, the maker of the famous Churchman's chocolate, has in his new manufactory one of these engines (improved by Mr. Jones, an ingenious millwright of that city) for the sole purpose of manufacturing chocolate and cocoa. With the consumption of this little article must far exceed our ideas, or, which we think much more likely, a very large portion of what is drunk in this kingdom must be made by him." This is the very thought that occurs to us after walking for hours over only one of the four main factories that rise aloft tier upon tier, with their tall smokestack, giving employment to more than two thousand people. Fry's had been established some half a century when the *Norwich* paragraphist quipped about the "little article" of cocoa, and yet with four factories *en bloc* and several outsiders there is still room for competition in the supply of the United Kingdom, which in 1891 paid duty on 21,601,825 lb.

The water supply for the eight sets of engines is obtained from the river Frome which runs under the factories a prisoner beneath stone arches, the old story of the bright and cheery brook arrested on its way through pleasant meadows for various industrial purposes, dammed up to turn a mill, then released for a brief freedom to be the playmate of village children, to floating tiny boats and murmuring beneath ancient bridges, finally to be caught and imprisoned under city roads and compelled to feed the boilers of hot and steaming-engine houses. If the Frome were sentient, the strong child of the Avon might be content to know that it was helping to produce the pretty boxes of chocolate creams that come to happy children at Christmas time, not to mention those canisters of cocoa extract that give wholesome drink to thousands of busy people. "We shall want a larger supply than the Frome can give us," remarks our guide, "when the new factory is finished," and he draws our attention *en passant* to a block of buildings in course of erection. Here we have an opportunity of noting the principle upon which all the factories are constructed. Each floor is supported by iron pillars, with girders and cross girders, the spaces between the girders being

filled with slate pavements; where stone is used it is Cornish granite. The completion of the new factory will increase the number of hands employed to between two and three thousand men, women and girls. It is a surprising story, the multifarious operations that belong to the production of a cup of cocoa or a chocolate cream.

Incidentally we ought to mention that traversing one of these factories and parts of the other four, making excursions over bridges from street to street, we have noted with pleasure evidences of the care both physical and moral which the firm takes of its work-people, more particularly of the younger members of their staff. More than once we have passed through meal-rooms and school-rooms. The firm provides the means of cooking in the factories, and the great majority of the young people only leave the works to buy their daily food or to supplement the tea and dinner baskets with some trifles from the adjacent markets. In one of the main factories we came upon a large and handsome lecture room which is also once a week used as a night school, once for boys and once for girls, the firm providing them with teachers. Every morning at a quarter to nine, one of the seniors of the firm attends in the lecture room and reads a chapter in the Bible; and a hymn is also read. The hall is occasionally lent to them for meetings of their own, the employers and employed are evidently on the best and most friendly terms with each other. There are also sick clubs and other organizations of great usefulness connected with the factories, and indeed the whole concern is conducted as if the persons engaged belong to a special community outside and apart from the busy city to which it has given the name of "the cocoa metropolis."

We have already seen how the growth of great industries has compelled manufacturers to extend their businesses in directions never contemplated at the outset. Fry's is a remarkable instance. Besides chocolate makers, they are engineers, boxmakers, carpenters, tinworkers, and are concerned in various other occupations. Beyond the factories we have described, we found ourselves driving in cabs and tramping through the ancient ways, visiting other concerns that belong to them and are an integral part of their main business. Our first visit was to Wapping, where they have a steam saw-mill with all kinds of implements, circular, whip and other saws, planers, nailers, and what not on the newest principles. The nailing-machines are ingenious contrivances; they work automatically, are fed with nails and supplied with boxes in sections which, passed from hand to hand, from machine to machine, are completed with remarkable rapidity. There is a new saw here, circular and pliable, which cuts two planks at one operation and does not need to be fed; one man gives it occasional attention. Fenced off in the mill are several printing machines for labelling the box lids. How many separate packets these boxes are made to hold it would be difficult to say, but the firm in its Wapping carpentry turn out some thousand dozens of them every week. After inspecting the mechanical work of the mill, we entered the store-rooms to find what almost seemed to be acres of boxes ready for use.

From Wapping we drove to the county gaol. It is many years since the present writer visited this once formidable house of detention, the occasion being the arrest of Sir William Don, while that "tall monumental warning" of reckless expenditure (as he called himself in one of his local speeches) was fulfilling an engagement at the Bristol Theatre in King Street. Those were the days before the abolition of arrest for debt, when the bailiff though shorn of much of his power was still a formidable officer. Sir William was a good deal put out when he was not allowed to finish the play in which he was acting; but great sympathy was shown for him, and he found exceptional accommodation at the castle, where the Governor, Mr. Gardener, gave up to him one of his own private rooms and made his brief incarceration as pleasant to him as possible. This included a very agreeable luncheon the next day, at which I was a guest. Sir William related to us some of his humorous adventures. One may be excused after all these years for feeling a curio

sensation at finding the little garden, in which one had walked and smoked after that breakfast with Sir William and the Governor, now occupied as stables for the large working team of Messrs. Fry, and part of the castle turned into a store for their box timber. But there are many other remarkable changes in Bristol, and it seems as if our guide had a curious facility for impressing them upon us. He takes us to Quay Street and introduces us to the card box factory of the firm. We had already in the stationery department of the main factory seen the cardboard cut into shape by various curious little machines and prepared for this outer shop. Here the boxes are made and decorated and the tops embellished in gold with the names of the firm. The atmosphere of one of the *ateliers* was full of gold leaf. Stray bits of it here and there looked like golden butterflies, their fanciful motion aided once in a way as to realistic effect by a ray of sunshine that came in through an open window. Throughout this building there were heard the cheerful voices of girls whose division of labour began with a plain bit of cut cardboard and ended in the perfected box.

Once more threading the traffic of the city, we come to premises where the firm has converted a comparatively new building into a store chiefly used for the Christmas fancy trade; here cases are being filled with chocolate dainties by scores of busy hands, while one floor is dedicated to the making of "orange flavouring," and a very attractive operation it would prove, we fancy, to most young people. Stacks of loaf sugar and baskets full of oranges are being used up. The oranges having been rubbed upon the sugar to extract the flavour of the rind, they are then returned to the baskets which are emptied into presses made on the principle of the cider-press. The juice is squeezed out with the impregnated sugar and the whole mass is full of the aroma—"orange groves and music from sweet lutes" might be added by the imaginative writer.

From Quay Street we pass on to Nelson Street, and here, like the cuckoo, the firm occupies another nest built for other birds. This time it is the old Trade School that has been annexed for a tin industry. The shops are fitted with remarkable machines that deal with tin as easily as if it were paper, cutting it, twisting it, making it into canisters round and square with the greatest ease, but not without a certain amount of noise and clatter. For instance, there are machines that at one operation make the tops and bottoms of canisters, embossing them at the same time with everlasting labels.

There are other minor industries in which the firm is engaged—they make much of their own machinery with the exception of castings, for instance—but it would need a week's stay at Bristol and an entire magazine to follow the ins and outs of this cocoa and chocolate industry. We have said nothing about its offices, its carts, its shipping arrangements, little about its history; nor paused to mention the political and judicial honours that belong to the family; these things are part of the history of Bristol; but luxuriously ensconced in a Great Western railway carriage, with a rack full of literary souvenirs of the western country, and one of those bright boxes of sweets made from the beans which the dusky mailers are collecting in our first picture, it would have been impossible not to think of a few parting words about the literature of this "food for the gods" that takes so many people to prepare and provides so many with pleasant refreshment.

White's in St. James's is the direct successor of White's Chocolate House, which is represented with St. James's Palace in the fourth plate of Hogarth's *Rake's Progress*. Chocolate was the excuse, gaining the object of White's. Yet the beverage was much drunk and very fashionable in the days of *The Tatler* and *Spectator*. The Cocoa Tree was also in St. James's Street. It was a Tory house. De Foe mentions it to remark that "a Whig would no more go to the Cocoa Tree, than a Tory would be seen at the Coffee House of St. James's." Eventually the Cocoa Tree, like many of the taverns and coffee houses of the time, developed into a club. As an instance of

the familiar terms which many of the men of fashion permitted between themselves and the monks of these famous rendezvous, it is related that a favourite waiter named Samuel Spring, having occasion to write to George IV. when he was Prince of Wales, commended his letter in these words: "Sam, the waiter at the Cocoa Tree, presents his compliments to the Prince of Wales, &c." Next day the Prince saw Sam, and after a quiet rebuke as to the freedom of the style of his note, remarked: "This may be all very well between you and me, Sam, but you will find it will not do with the Norfolks and the Arundels."

These passing thoughts with a few mental memoranda as to the literature of White's, and the Chocolate House, have scarcely been supplemented by a glance at the evening papers when we run smoothly in a Frith's Railway Station, having made the journey of a hundred and eighteen miles in the time that it would have taken the wits of St. James's to get from the Cocoa Tree to Richmond.

A PERAK COFFEE ESTATE.

The following notes by Sir Graeme Elphinstone are on the Waterloo Arabian Coffee Estate, Perak, and are from the *Perak Government Gazette*:—

ELEVATION.—The elevation of the average of the present opened area of Waterloo, and also of the surrounding forest, which I consider most suitable for the successful cultivation of Arabian coffee, is some 2,300 feet.

This elevation is similar to the elevation of what in Ceylon was termed the lower districts, but, although similar in that respect, there is a very marked difference in the temperature, and certainly the comparison is favourable to Waterloo. I presume that the comparative coolness of the Waterloo climate is mainly attributable to the fact of there being so large an adjacent area of high mountain ranges covered with virgin forest, and also to the close proximity of the sea.

Anyhow, there is no gainsaying the fact that at the elevation of the present bungalow, some 1,850 feet, the climate is both pleasant and salubrious.

QUALITY OF SOIL.—The present opened area of Waterloo is in extent some 270 acres. In the opened land there are four distinctly different qualities of soil, and all of them seem to be very suitable for the successful growth of coffee. Dr. Ridley, who visited Waterloo last month, was highly pleased with the nature of the soils he passed through, and agreed with my opinion as to their fertility; there is a very good average depth all over the estate of some 20 feet (this is a much greater average depth than in any district in Ceylon). I cannot speak with any certainty of what the soils may be deficient in, as I have not as yet been able to get samples analysed; but if, as both Dr. Ridley and I believe, there may be a deficiency in lime, this deficiency can easily be supplied from the adjacent lime-kilns. However, that is as yet merely a conjecture, and at no very distant date I hope to have more certain information to work upon.

ASPECT.—In Ceylon we always preferred an eastern aspect, and here I find, from careful observation, that it is of equal importance. Waterloo has an almost uniform eastern aspect, and this, I consider, reflects considerable credit on those who first selected the land. Whenever I select land for coffee, I shall most certainly be most careful to select forest land with as much of an eastern aspect as can be obtained, and I would certainly advise intending planters to be careful on this point.

RAINFALL AND CLIMATE.—The information I can gather from the estate books leads me to believe that the total annual rainfall is some 95 inches, and this, apparently, divided over the twelve months; but, for want of exact records, I cannot speak with certainty as to the amount. Now a careful record is kept, and will furnish correct data to go upon. From personal observation since the date of my arrival on the 11th December, 1891, I have noted the fact that on no single day has there been continuous rain, and on

no single day have we been without some sunshine. This is very different to the average of the Ceylon coffee districts: there it is a frequent experience in both monsoons to have incessant squalls and heavy rainfall with a complete absence of sunshine, sometimes for ten days to a fortnight. The effect in Ceylon of the heavy rains and absence of sun-heat is very marked, and has a most prejudicial effect both upon the yield and the vigour of coffee and tea. I have also noted that the sun-heat is of greater strength here than in Ceylon, and it is most beneficial, as it acts favourably on the strong soils, pulverising and drying the soil down to a depth of fully 15 feet. This, again is of benefit in the prevention of wash. In Ceylon, a heavy shower in the rainy season simply runs over the surface; here on the contrary, it passes down the sun-cracks and thus fertilises the soil.

CULTIVATION—WEEDING.—The great importance of keeping clearings clean and in hand, weeding from the commencement, has been the Waterloo experience. The sunshine and showers, which are almost daily, favour a growth of weeds almost incredible, and I am of opinion that it is a *sine qua non* for successful planting—clean weeding from the date of the burn.

PRUNING AND HANDLING.—From what I have observed, I believe that, with careful and judicious treatment of the bushes from the commencement, knife pruning would not be required. Handling is most important. Great care must be taken in keeping the centre of the tree for 6 inches entirely free of wood, and the outside branches must be carefully and systematically singled out so that the lower primaries may not be excluded from the light. The same effect experienced in the growth of weeds, caused by the sunshine and showers, is also to be found in the growth of young wood, and it is essential for the health of the bush, as well as for regular bearing, that the wood should be limited to what is actually required.

MANURE.—The opportunities for cultivation, on a liberal scale are all that can be desired. There is an abundant supply of lime, a similarly abundant supply of bat guano, and, from the fact that both Guinea grass and the native grass grow with such luxuriance, cattle can easily and profitably be kept. This is a most important fact, for in Ceylon many a good estate dates its decline from the date that it could not obtain the necessary help from cattle manure.

LABOUR.—On the point of the labour supply there will, I expect, for several years yet be a difficulty. The Tamil labour will gradually increase, and once more estates are opened there will, I believe, be a supply quite equal to the demand; but it would be folly to consider planting at present impracticable because Tamil labour is not yet completely organised. I have, through necessity, been obliged to employ Malays, Chinese and Javanese. I have found them all most efficient workmen. I am exceedingly glad that I have had cause to employ others than Tamils, otherwise, I might have continued in ignorance of the valuable labour supply locally available. I cannot at present fully particularise on this subject, but I will do so at a later date, and will supply figures showing actual cost of work done by Chinese, Javanese and Malays, which will compare favourably with what is done by the Tamil in Ceylon.

SORGHUM.

Sorghum has been used as a forage for stock in this country for many years. As such it is adapted to a wide region, and its cultivation has extended over the entire extent of the United States. In other countries it has been used for the manufacture of sprits, glucose, beer and vinegar. Its seeds have been used as a food for man and beast, and in this country a large part of the profit of growing sorghum consists in the value of its seed as a stock food. For nearly thirty years syrup has been made from it, and during that time high hopes have been entertained of its power to produce profitably sugar. The attempt to make sugar from sorghum has

been made almost exclusively by Americans. In China, where the sorghum has probably been grown for thousands of years, we are told by Dr. S. Wells Williams, Professor of Chinese in Yale College, that there is no evidence that it has ever been used for either syrup or sugar making.

It is curious to read in the earlier publications on sorghum, the contradictory opinions and opposite views so positively asserted by the authors. As to the kind of sugar present; the best varieties; the period of growth; of maximum sugar content and the exact time to work after cutting, nothing was known definitely until the beginning of the scientific investigations by the National Department of Agriculture in 1878. Since that time this Department has assiduously continued its investigations in sorghum, and while we write the Fort Scott experiments in diffusion and carbonation are being brought to a conclusion by the eminent government chemists. The publications of this department upon sorghum since '78, have been numerous and instructive and to-day every farmer has within his reach valuable and definite information in regard to this plant, the result of patient investigation conducted by trained scientists at government expense.

BOTANICAL RELATIONS OF SORGHUM.

Sorghum is one of those plants, whose origin is utterly unknown. By long cultivation, its habits and characteristics have been so changed that no resemblance can now be found to any wild plant. Formerly the different cultivated varieties of sorghum were regarded as distinct species, but modern botanists have been gradually led to the conclusion that all our sorghums and juphees, including broom corn, chicken corn, durra, nilo maize, etc., are but varieties of a single species—*Sorghum Vulgare*. These conclusions have already inspired many seedsmen, farmers and scientists with the belief, that ultimately by selection of seed, proper fertilization and cultivation, a true sugar bearing sorghum may be obtained, which can be profitably grown and worked, instead of the true sugar cane or beet. Differentiation in plants is accomplished by extending the area of cultivation, taking in differences of soil, climate, rainfall and manures; by careful selection of seed; by cross breeding, etc. In this way varieties are produced. Some plants have greater capacity for variation than others, and sorghum is perhaps surpassed only by Indian corn, in its tendency to assume new varieties under changed conditions. Hence we find a large number of varieties of sorghum on our market, differing in every conceivable character, from content of sugar to color of seed. It is therefore of first importance in growing sorghum to select those varieties best adapted to our wants, remembering the modifying factors of soil, climate and manures.—From Bulletin No. 5 of the Louisiana Sugar Experiment Station.

NEW JOINT-STOCK COMPANIES.

The following tea company has just been registered:—Maybloom Tea Plantations, Limited, with a capital of £50,000 in 10 shares. Object, to acquire, either in India or any Colony or dependency of the United Kingdom or elsewhere, land suitable for the cultivation of tea, coffee, cinchona, &c., to stock and manage the same, and generally to carry on business as tea, coffee, &c., planters and merchants, brokers, &c. The first subscribers, who take one share each, are:—E. G. Rock, 1, Great Winchester Street, E. C.; T. H. Trotman, 69, Highbury Quadrant, N.; O. H. Wellard, 10, Gray's Inn Square, W. C.; J. W. Aubrey, 55, Dalview Road, Stamford Hill; T. E. Munday, The Poplars, Buckhurst Hill; Gr. R. Davey, 4, Fasset Road, Dulstou; O. T. Wale, Bonne Hill, Palmer's Green, N.

The business of the company is to be under the control of managing agents, the first being the Planters' Stores and Agency Company, Limited. No particulars given as to qualification or remuneration.—*H. and C. Mail.*

THE TEA ROLLER PATENT CASE.

DECISION AGAINST JACKSON.

In the District Court of Colombo today (May 2nd,) Mr. Owen Morgan gave judgment in favour of the defendants in the action for infringement of tea-roller patent, Jackson v. Colombo Commercial Company and Brown. The following is the full text of the deliverance:—

This is an action for an injunction to restrain the two defendants from importing into the island and using and selling the tea-leaf rolling machine known as "Brown's triple action tea-roller," and from otherwise infringing an invention of the plaintiff's for the rolling of tea-leaf for which he had acquired certain patent rights. The plaintiff also prays for an account of all gains and profits derived by each of the defendants from the importing and using and selling in the island of tea-leaf rolling machines infringing as aforesaid.

The plaintiff alleges that he was the first and true inventor of a certain new and useful invention for improvements in machinery or apparatus for rolling tea-leaf as declared in his specification and called "The Excelsior."

The defendants deny that plaintiff was the first and true inventor of the invention by him alleged to have been now and useful, or that it is new and useful or that the specification filed by plaintiff describes the nature of the plaintiff's invention, or that the defendants infringed any exclusive right granted to the plaintiff and they allege that the first defendant (as the importer) is the inventor of the invention known as "Brown's triple-action roller," and that the same was an invention new in Ceylon and was not only useful within the requirements of the requirements of the Invention Ordinance, but possessed an utility as a tea-roller far superior to that realized by any machine designed or constructed by the plaintiff.

The specification filed by the plaintiff states that he is in possession of an invention for improvements in machinery or apparatus for rolling tea-leaf and he therein describes the nature of the invention and in what manner the same is proposed. In figure II of the drawing filed with the specification, A is the top-rolling surface usually composed of wood, B is a case or jacket loosely enclosing the rolling surface A so that it (A) can be weighted to give the required pressure to the leaf and can be raised or lowered within the jacket by means of the chain C for the purpose of feeding the machine from the hopper D; and E is a bar firmly attached to the case B and arranged to slide in the bearing F which together with the crank P in K carries the case B and prevents it bearing its weight on the under table at any time although the case B actually comes nearly in contact with it. Having described the nature of the invention and the manner in which it may be used, he asserts what he considers novel and original and therefore claims as his invention three arrangements or combinations, the first of which only the Court has to deal with in this case, for that is the infringement which plaintiff complains of. It is this: "The arrangement of transmitting motion to the top rolling surface through the case or jacket surrounding it whereby such rolling surface is left free as regards vertical movement from the mechanism operating it." That is the invention in the Excelsior which the plaintiff complains has been infringed by "Brown's triple-action roller."

The first machine for rolling tea leaf which the plaintiff also claims as his invention and which he calls the Standard, was a machine which plaintiff invented in India and which he patented there. This machine involved him in India in litigation with Kimmond who asserted that plaintiff had infringed his patent in respect of a machine which he had previously invented, and the plaintiff was obliged by arrangement with Kimmond to manufacture the Standard under a license from Kimmond. The Standard was never patented in Ceylon and only

one of the Standard was sold in London and imported into the island and worked on Loolecondra estate. The jacket of the Standard rested on the lower surface, and its heavy weight made it stiff to drive. The driving mechanism of the Standard was connected with the upper plate or surface or cap, the jacket surrounding the cap being left free or loose. It was an expensive machine, and a good deal of time was wasted in getting the leaf through the centre of the cap. The jacket had to be made heavier to prevent jerking and jumping whilst in motion. This led the plaintiff to contrive a machine which was less costly and more easily driven and he hit on the Excelsior which he states is just the converse of the Standard. In the Excelsior he took the driving mechanism from the cap and attached it to jacket, and this machine proved to be a great improvement on the Standard.

There can hardly be any doubt that the plaintiff was the first and true inventor of the Excelsior and that it was a novel and useful machine. The only question remaining for consideration is whether the defendants' "triple action roller" has infringed the arrangement in the Excelsior of transmitting motion to the top rolling surface through the case or jacket surrounding it.

The case or jacket, the plaintiff asserts, consists of a wooden case attached to a metal frame and secured to it by bolts—all forming one piece and designated by him "the case or jacket."

The top or upper rolling surface moves vertically and can be raised or lowered into the case or jacket which loosely encloses it.

What is the case or jacket of the Excelsior? Is it the woodwork or wooden lining combined with the metal frame to which it is attached, or is it the woodwork or wooden lining alone? In appearance the whole upper part of the machine is one piece, and can be tilted up in its entirety; nevertheless it consists of two distinct parts—the metal frame and the woodwork or wooden lining. This metal frame, by whatever name it may be called or whatever shape it may assume, is still what engineers call "a connecting rod," for it has all the adjuncts or parts which constitute a connecting rod. It takes the form in the Excelsior of a metal frame or plate, and is so attached to the crank pin at one end and the guiding rod at the other, that it may be the means of converting circular into rectilinear motion. There has been a good deal of conflicting evidence on this point, but the weight of testimony is in favour of the defendants' contention, that the metal frame is a connecting rod, and that the case or jacket is the woodwork or wooden lining alone; that the metal frame is a part of the driving mechanism of the machine and gives motion to the woodwork or wooden lining, this woodwork or wooden lining being the case or jacket which drives the upper rolling surface.

Upon the evidence it is abundantly clear that the upper rolling surface receives its reciprocating and horizontal motion entirely through the woodwork or wooden lining, which is truly the case or jacket by impact with it, that is it receives its motion from the case or jacket immediately adjacent to it. If the case or jacket is removed the upper rolling surface would have no motion, except the vertical movement upward and downward which it has quite independent of the case or jacket, acting merely as a weight on the tea leaf and giving pressure to it.

In the triple action roller motion is not imparted to the upper rolling surface by or through the case or jacket. The upper rolling surface has no impact whatsoever with its case or jacket. The whole machine can be worked and motion imparted to the upper rolling surface without the case or jacket. The upper rolling surface has it: horizontal as well as its rotary motion complete, and quite independent of the case or jacket. The machine is complete without the case or jacket, for, it was removed from the machine and it worked perfectly.

Both machines—the Excelsior as well as the triple-action roller—have the same object in view; both

have a lower and upper rolling surface and a case or jacket; but in the Excelsior the case or jacket not only holds the tea leaf, but it also drives the upper rolling surface and transmits motion to it, whilst in the triple-action roller the only use to which the case or jacket is put is to hold the tea leaf and that appears to be its only office. As the Excelsior was an improvement on the Standard so the triple-action roller is an improvement on the Excelsior, and is decidedly a far more efficient and satisfactory machine.

On the whole I am of opinion that the defendants have not infringed the plaintiff's right by the arrangement of transmitting motion to the upper rolling surface though the case or jacket surrounding it, and that plaintiff's action must be dismissed with costs.

OWEN MORGAN, D.J.

PETITION OF APPEAL.

In the District Court of Colombo.

William Jackson of Aberdeen, Scotland, Plaintiff and Appellant, vs. 1. Alfred Brown of Colombo, 2. The Colombo Commercial Company, Limited, of Colombo, Defendants and Respondents.

On this 5th day of May 1892.

To the Hon'ble the Judges of the Supreme Court of the Island of Ceylon.

The petition of appeal of the abovenamed plaintiff appearing by his Proctor Mr. F. Liesching states as follows:—

Your petitioner feeling aggrieved by the judgment of the learned District Judge dated the 2nd day of May 1892 begs leave to appeal therefrom on the grounds

1. That the issue of infringement has alone of all the issues in this action been decided against your petitioner, and it is humbly submitted that the learned Judge's verdict on that issue is contrary to law and against the weight of evidence.

2. It is contrary to law because in determining this issue, and for that purpose enquiring into the nature of the invention alleged to have been infringed, the learned Judge has governed himself not as he should have done by a consideration of the language of the specification in which the invention is described of the circumstances under which this instrument was framed of the kind of machine to which it relates and the class of persons to which it is addressed but by the opinion of skilled witnesses as to the function and terminology of the various parts of a machine, treated rather as a model for the illustration of mechanical principles than as one designed for the manufacture of a useful commodity.

This is indicated by the learned Judge's remark that the triple action roller could work perfectly well without the case or jacket. So it might, perhaps as a piece of mechanism in a laboratory but it would not be an efficient machine in a factory.

3. The real question involved in the issue of infringement is what did your petitioner mean by the word "jacket" in the specification of his invention as illustrated by the accompanying drawings, and if they are examined as made and addressed by an inventor to workmen of competent skill and acquainted with this class of machinery there can be no room it is submitted for doubt that it must mean and could only have meant the case confining the tea leaf with its bow bracket and general bearings as a whole and the best available evidence is all on one side as to the correctness of this information.

To treat the pieces of wood which when fitted together compose the case in which the leaf is confined as an integral part of the machine disconnected from its other constituent parts and to confine the word jacket to that wooden case is to make it insensible for the purposes of the invention described in the specification and contradicts the very language of the specification with its drawings.

4. If the jacket as your petitioner contends comprises the case, it supports the bearings, bow, bracket, &c.

i.e., in fact all the parts above the lower rolling surface except the lid which controls the pressure of the leaf in operation it is self-evident from a comparison of the machines in work that the principle of the "Excelsior" invention "the arrangement" to wit of transmitting motion to the upper rolling surface through the case or jacket surrounding it has been taken over by the "Triple Action" machine of the defendants.

Wherefore the petitioner prays that the said judgment dated the 2nd day of May, 1892, may be set aside and judgment entered for the plaintiff as prayed in the plaint and for such further and other relief in the premises as to your Hon'ble Court shall seem meet.

(Signed) F. LIESCHING,

Proctor for Plaintiff and Appellant.

THE PLANTING DISTRICTS OF SOUTHERN INDIA.

As the first districts we propose to refer to are those in which coffee is cultivated, a brief résumé of the life of the coffee planter throughout the year will be of interest. It is one of the most popular fallacies of human nature to presume that everyone, whose method of work and whose work itself is not identical with his own, must therefore be enjoying an easy and a lazy life. The man across whose brow course perennial streams of sweat refuses to admit that he, who is able to keep cool with the thermometer over 80 and is not ever on the fidget and fret, can honestly earn his bread. So it is argued by him in tea that the planter who is not ensued with a factory rejoices in a life in which beer and skittles preponderate largely. No doubt the coffee planter is spared much anxiety by not having to be on the watch continually to see that his produce is not ruined in the preparation of it, but this anxiety is made up to him in various ways—by the many changes and chances of weather on which his whole crop depends, by the numerous enemies to the berry itself against which he has to guard, and by his having to entrust the preparation of the bean entirely to others, with whom he is often not on the best business terms.

The work of the coffee planter, who has an old estate and is making new clearings, may be generalized as follows in the majority of the planting districts in Southern India. In January he commences his felling in order for the timber and brushwood to be well dried to burn off before the first showers fall towards the end of February or beginning of March. So soon as this work is over, lining and pitting go on apace, for labour is scarce through the hot months of March, April and May; and though the planter may reckon on having the best part of three months in which to plant, yet the south-west monsoon is as fierce as the fair sex, and the wise man will prepare so as he can take advantage of every burst of the monsoon as though it were the last. In June comes the monsoon. Then the rule is that there is more work to be done than hands to do it—planting in the new clearings, weeding in the old, to be followed by pruning, digging and manuring; and while the sun is up the planter has but little time to cool his heels in his verandah until September, when work eases off a little, and advantage is taken to enjoy ten days' holiday either in assisting at week festivity or a stork after bison and big game, or a visit to the hospitable homestead of some distant friend. Thus will the coffee planter fortify himself against the multitudinous warricks and annoyances which are rife while "crup is on." In October he commences his preparation for the great event of the year, and before the middle of November small gangs of women and children will be put on for a "fly-pick." It may be the middle of December before the crop really begins to pour in, and the whirl of the palper is heard in the land and the watch-fires are lit by the barbeques and the time of the coffee theft is at hand. These are days of intense anxiety, it is with a deep and sincere sigh of relief that the respect for the last bandy load of parchment is received from

the Coast curers, and the cash for the lsils and refuse counted out by the local native merchant. January will be often on the wane when this consummation is arrived at, and then there will be another two or three week's work, clearing up, pressing the old coffee, manuring the fields shaken by overbearing, &c., &c. So the year wears away. In the hot weather there is usually an exodus for six weeks or two months, for a good 'writer' is capable of superintending new clearings up to a certain point, more especially if a stay-at-home friend can be found who will ride over once or twice a week and see everything is going on all right. The Shevroys in the Salem District and the Pulaveys in Madura get but little of the south-west monsoon, the north-east being the one on which they depend, and so the foregoing hardly applies to them.

As regards the climate which the coffee planter of Southern India enjoys, it is varied but good, except that at some seasons and in some districts malarial fever is prevalent. As the elevation of coffee cultivation varies from 2,000 feet to 5,500 feet, the temperature, of course, different: but Wynaad, where the estates are on an average at just under 3,000 feet may be taken as a fair average. The south-west monsoon usually begins in the first or second week of June. Then the flood-gates of heaven are opened, and the rain beats down in torrents, and the Zephyrus rage and bluster: but it is in July when the heaviest and longest burst takes place. This climate is not nice, for, equally with nature out of doors, your books, your boots and your head assume a verdure, which is dispiriting. However, cracking wood fires and hot toddy can be indulged in in comfort, and there are many things more unpleasant than of evening to sit in front of the one and with the other beside you while 'nude' the stormy winds do roar and the rain comes down in torrents. Presently there will come a break and a few days of the most glorious weather that ever gladdens this dear old "vale of tears;" days such as that one must have been at the dawn of which "the stars of the morning came together and all the song of God shouted for joy." August is sometimes beautiful and fine, sometimes dem'd moist and unpleasant, and so September: in fact these months take it in turns to be one or the other. October is a month of lovely mornings and wet afternoons, the north-east monsoon being about to declare itself, wherefore thunderstorms are rife and heavy downpours frequent, in which a inch or more of rain will fall in less than an hour, much to the annoyance of the planter whose land is steep. The mornings in November grow crisp and cold, wisps of snipe are in the swamp, the hell of the sambhur is heard on the mountain side, and life is as full of sport as work allows and very much worth living. December and January are glorious months with a climate that would make the fortune of the district many times over if it could only be transported to Europe or the States. Fires blaze in the hearth at nights and in the mornings the planter blazes in the swamps, which are frequent and hold many snipe, and while tramping through them an occasional shot at a jungle sheep or spotted deer may be got and no little excitement worked up over *khubber* of hear, panther or tiger in an adjacent *shola*. February is rendered unpleasant by a raging and tearing N.-E. land-wind, which dries up everything, curls up the backs of your *éditions de luxe*, and converts your cheroots into tinder. At nights beacon fires flare on all the hills, a glorious sight to gaze on from afar, but not so pleasant should the fire commence tearing down the hill above the stables, the flames leaping and rushing and frolicking through the tall jungle grass and scrub like a herd of wild horses at play. The whole country-side becomes black and burnt up, and a heavy mist of smoke lies over the land. Before March comes in thunder is heard remote, and each night the lightnings blaze and flash and quiver along the distant horizon. The mornings are hot and sultry and every afternoon black masses of cloud, big with the rain that means fortune or disaster for the planter, roll heavily across the sky. At length the rain falls in blinding sheets, and from the grounds there goes up

that strange fragrance all know so well, like a song of thankfulness from a thirsty land. In a very few days everything is green again, save the fields of coffee which are covered with the sweet white petals of the blossom for which the planter has been waiting so anxiously. April is much the same as March—suntrines followed by heavy thunder-storms, then a few days of refreshing coolness. In May the weather continues broken, and the middle of the day very hot, but the mornings and evenings are deliciously cool and fresh; and so on till the monsoon again breaks. This is the climate of the Wynaad, and it is very similar in other districts. No little rain interspersed amongst days of the most glorious and perfect weather.

The present Government of Madras has at length realized that the planting industry of Southern India which brings into the country a crore or two of rupees per annum, and is a very present help in time of famine and distress to the ryots and labouring classes of Southern India, deserves encouragement, and the planter is beginning to feel that he has but to represent his case to receive consideration at the hands of Lord Wellesley and his advisers. Slowly and by degrees that curious delirium of the brutal planter, is fading from the walls of the Council Chamber where it has figured for so many years, and he is ceasing to be looked on as that strange specimen of obsolete feudal barbarity, who when not wallowing in whiskey and waltzes was dancing a waltz on the spleens and the domestic virtues of his coolies. The weakness of the planting community of Southern India consists in its being under the rule of so many different Governments; for while Wynaad, the Nilgiris and the Shevaroyas are under the Madras Government, Coorg is under the Government of India, the Mysore and Travancore planting districts are within the boundaries of these native states, while the N. Lamphthies belong to Cochin. Here we will draw to a close and reserve our description of the districts themselves for another week.—*Indian Planters' Gazette.*

THE PIONEERS OF NORTH TRAVANCORE.

(From One of Them.)

From time to time you have admitted to your columns fugitive communications from the planters, or to speak more correctly, from the pioneers, who have for the last ten years been engaged in opening out the northern portion of the Travancore State to planting enterprise. It will be remembered that the main obstacle in the way of settling the extensive and salubrious range of mountains and valleys which are known by the name of the Kannan Devan Hills lies in the difficulty of access. While the estates were in a state of childhood, not yet having reached the productive stage, the absence of roads did not much affect the formation of estates. Forests have been felled, nurseries formed, plants have been set out and even bungalows built (though at great cost) while all the tools, rice, stores, roofs, and building materials necessary for the above objects have been carried up from the plains on pack cattle, ponies, donkeys and on men's heads. Time has meanwhile been rolling along, and the plant has developed into a bush, the cinchona seedling into a tree. The years have at length rewarded the settlers, and they pride themselves with thousands of pounds of bark, tons of coffee, and sheats of tea. But now has come into play the question of cost of carriage, and the delay and expense of pack animals seriously handicap the exporters when competing for markets with produce from other planting Districts where carts take the crop from the planters, then to the railway station or port without break of bulk. However these planters are a self-reliant body, They

always have in the mind honest Sancho's solution that there is a remedy for everything but death, so by dint of importuning the Government of Travancore, harassing the Resident and petitioning the Governor in Council, and out of Council the planters have at last the satisfaction of knowing that a cart road has been sanctioned, funds provided by the Travancore Government, and that in a short space of time, carts may come rolling up with rice and tea box fixings and rolling down with wealth "beyond the dreams of avarice." This cart road, which will come out into the Coimbatore plains some 20 miles south of Udamalapeta, which again is 40 miles from the nearest railway station, will immensely improve the prospects of the planters and should lead to a very considerable increase in the number of properties opened out in these hills.

There is no other place in India or Ceylon where such facilities exist for the acquisition of planting land. The Directors of the North Travancore Land, Planting and Agricultural Society seem to have profited by all the dinning and dunning regarding easy purchase of land which have been in all the newspapers for ever so many years. I learn that a man on the look out for land can go up to Devacolum, select his block, have his application registered, pay down his money and take up possession within as short a time as suits his convenience. There is no bother about stamped application, or waiting till Collector Sahib has had the land inspected. The Agent has only to see that no one else claims this block, and our eager planter can become master of his acres, and put down his nurseries, and fell his forest and build his preliminary huts—all in the rub of Aladdin's lamp. If he ventures in cinchona—and a wonderfully cheap and profitable venture that same is, notwithstanding low prices—there are estates all round him where he can decide on the sort best suited to his bit of land, and purchase seed or plants as may please him. If he goes for coffee, he can have his pick of thousands of acres of virgin forest all at R15 to R25 an acre. Tea is in the same category. 'Tis extraordinary to see the output of tea at so high an elevation. Five hundred pounds of made tea to the acre off four or five years bunches, and at an elevation of 5,000 feet too! However, until the road is finished, the best way for the new man is to go to Ammanayakanore, on the South India Railway, thence by bullock transit to Bodinaiknors, whence a bridle path leads to the Land Agent's bungalow at Devacolum. There are, as I say, great quantities of forest land at an elevation of 5,000 feet available for tea and coffee, but I must guard your readers from supposing that there is very much forest suited for cinchona above 6,000 feet. No doubt a few thousand acres still remain, but it is being rapidly absorbed by planters, for, in point of fact there is now no place either in India or in Ceylon where such land is to be got. Pleasure and profit attend a settler in these altitudes, where the delicious climate, pure water and healthy life really make life worth living; where a man can rear his estate and rear his family and make unto himself a home to last for his life and for his son's lives; where he can grow cinchona and tea, and make 50 per cent. on his capital; where he can teach his boys to pull the ibax by the beard, and adorn the walls of his bungalow with tusks and horns, and where his girls lose not their roses, nor his wife pine away with fever and longing for the absent faces—for what shall it profit a man if he gain the whole world and lose his own health, and what can a man give in exchange for his health!—*M. Mail*, April 8th.

NAGAMALLY TEA COMPANY, LIMITED.
(TRAVANCORE.)

In submitting the report and accounts for the second year of the Company's working, the Directors congratulate the shareholders on the results proving better than were anticipated.

When the last Annual Report was issued there were in all 367 acres under cultivation, of which 120 acres are now yielding tea, and a small field of some 7 acres in coffee and spices; since then about 220 acres of forest have been felled and are now being cleared for planting with tea, and the intention is to go steadily on extending the area under this cultivation.

The estimate of tea for past year was 60,000 lb. and the quantity despatched from the estate amounted to 62,030 lb.

The coffee crop for 1891 proved a very short one compared with previous year, being only 9 cwt. 3 qrs. 17 lb.

The spices harvested amounted to 649 lb against 137 lb in 1890.

The estimate of tea for 1892 is 80,000 lb and may probably be exceeded, and the time has now arrived for the Company to provide itself with a permanent factory and with efficient machinery. Plans and estimates for these are now being prepared and materials collected for an early commencement of the work.

It is hoped, in addition to improved manufacture of the Company's tea, that they will secure an extension of the manufacture of tea for neighbours, which it will be seen from a credit item in the crop account is not unprofitable.

The amount at credit of profit and loss account is £494 12 6

Out of which the Directors propose to pay a Dividend for the year at the rate of 5 per cent. per annum, absorbing 442 2 4

Leaving a balance to be carried forward of £52 10 2

Of the second issue of 1,000 shares, up to date 325 have been allotted, and the balance of 675 shares will be placed as opportunity offers.

The Board desire here to express their satisfaction with the conduct of the Company's affairs by their Local Manager, Mr. F. W. Bennett.

FERTILIZERS FOR PEACH TREES.—At one of the New York farmers' institutes, Mr. G. T. Powell, in reply to the question, what is the best fertilizers for peach trees? said: "A fertilizer high in the element of potash is preferable with me; phosphoric acid is also necessary to perfect the seed. I find wood ashes, if they are good, one of the best fertilizers for peaches, as they contain both of these elements of plant food. Do not feed them too much nitrogen, as it induces too large a growth of wood which if continued late in the season, will not ripen."—*Rural Californian.*

GOOD PLANTING—Meehan's Monthly for February publishes the following: "It is not unusual to hear people say that they cannot understand why trees die on or transplanting, considering that they give the planting the very best of care. What is considered the best of care is often very bad care. It is amazing to see the careful planter without experience, occasionally on his knees pressing the earth in around the roots with his fingers, for fear of crushing the fibers. It is impossible to get the earth properly packed around roots in this way. In nurseries, where it is presumable planting is thoroughly understood, a man stands with a rammer while one is putting in the earth, and hammers the earth in as tightly as though he was hammering in a post. This packs the earth in more tightly than can be done by either feet or hands. Some are afraid of crushing the roots with this hammering process; but with the pressure all around, the force is directed towards the roots and not away from them. It is not necessary, however, to go into reasons, as the universal experience of the nursery is in favour of hammering in the earth as represented. This is the essence of good planting, and any other planting is decidedly bad. Trees properly planted need no staking. The fact that a tree needs staking is a proof that it was not properly planted."—*Rural Californian.*

IMPORTANCE OF MOISTURE.—The importance of moisture in fruit culture is strikingly illustrated in the writings of the late Charles Darwin. Respecting the district around Chiloe he says: "The town is situated on the low banks of the stream, and is so completely buried in a wood of apple trees that the streets are merely paths in an apple orchard. I have never seen any country where apple trees appeared to thrive so well as in this damp part of South America. On the borders of the road there were many young trees, evidently self sown. The inhabitants possess a marvellously short method of making an orchard. At the lower part of every branch small brown wrinkled points project. These are already to change into roots, as may be seen where any mud has been splashed against the tree"—*Rural Californian.*

TEA IN WYNAAD.—The *Mudras Times* of 10th May says:—

Our South Wynaad correspondent in an interesting and amusing letter which appears in another column tells us of inability to send any news about tea in Wynaad. We are in a position to state that beyond 75 acres which are being opened by a large Company at Oberambadi, there will be no extension of tea cultivation in Wynaad this year. More's the pity! The enormous increasing exports from Ceylon have evidently made capitalists at home 'scary' of this product, and we are afraid it will only be when Wynaad has proved beyond a doubt that it can produce tea of a quality which is able to hold its own with consignments from that island, that money will be forthcoming to any extent for opening out land in tea. Ceylon, from a tea-grower's point of view, can only beat Southern India in two respects: the climate with its regular rainfall, and the assurance of labour all the year round. The latter is the most important of the two. The best jāt teas there are undoubtedly behind those grown here, while on most of the estates the plants are of a very poor jāt indeed. The soil of Ceylon, as well known, is behind that of Southern India, but this is compensated for by the climate. The quality of Ceylon tea is deteriorating each year, more especially on estates where manure is not used, and we believe that the output per acre is also less. Fortunately for Ceylon there is a cohesion among planters, which is unknown here, and next to the United States there is no country that has so thoroughly mastered the art of advertising. Planters in Southern India will have to wait yet awhile before money comes to this country to any extent, and the only thing to be done is to keep their districts well before the notice of the public at home.

THE MANUFACTURE OF TEA IN LONDON.—In a recent letter I told you that I had been making tea from leaf plucked from ten plants, grown from imported seed in Mr. Foston's palm nurseries at Rye Hampton, Putney. It may not be without interest to some of your readers to know how I am getting on. I have not had much of a flush as yet, and have only had small quantities of leaf to work at a time, the plants flushing very irregularly; and the leaf has not been satisfactory. My last plucking was very small, but it is, I think, a curious instance of what may be done that though the leaf was so wet when plucked in the morning about 10 a.m. I had to toss the water off it, yet I was able to wither it, to roll it, to get it to ferment in some degree, and to fire it, and convert it into passamb tea, before 6 p.m. the same day. The liquor proved fair, and after standing some time creamed well. It had a rather greenish and slightly oolong flavor, probably owing to the hasty way in which I had been compelled to make the tea, as I had to leave town next day, and to his not being well fermented. The plants are now in a hotter use, and I hope to have a more even flush soon, and more time to turn out a larger quantity and a better sample. As I said, I am curious to know if this is the first attempt which has been made to manufacture tea in this country from English-grown tea leaf. Be this as it may, I fancy no one else ever made tea, from green and wet tea leaf in London before in one working day of eight hours.—*Cor. in local "Times," May 12th.*

FROM THE METROPOLIS

LONDON, April 15,

CEYLON TEA IN AMERICA.

I had the pleasure this week of meeting Mr. Elwood May as well as Mr. Grinlinton and of learning a good deal about places and prospects connected with our staple product in the Far west. From what I knew of America, I was able to test with some degree of authority the utterances of Mr. May, and generally I was impressed very favourably with the good sense, the determination and straightforwardness of the head of the Ceylon American Company. What he has accomplished in respect of advertising Ceylon tea in a large proportion of the leading newspapers in the States is quite astonishing, the more so as in all his contracts extending generally for twelve months, no cash has passed, the remuneration being taken in stock of the company. This has been accomplished in the face of Mr. May's frank avowal in each case that the value of such "stock" is still problematical and altogether in the future. Still the evident belief of Mr. May himself and of a large number of influential friends whom he has converted and whose testimonials he holds, to the superiority of Ceylon tea, has told in the newspaper world, and the result is seen in the following extract from the letter of a well-known New York Press Manager (a personal friend of my own) whose words I have been allowed to copy:—

"I want to say, as a parting word, that the contracts for advertising, which you have made, surprise me, both in their amount and the character. You have done, I am sure, what no other man has ever accomplished in securing many of the very best papers in the country, and placing the stock where you will not only receive very valuable space for it, but will secure the good will of papers who have great influence with the public."

It is impossible not to anticipate good fruit from such extensive and continuous advertising as has thus been arranged for. But Mr. May himself is not over-anguine—indeed I was almost going to say, he is despondent. He has full faith in pure Ceylon tea as a good article worth "booming," and he knows how it can be made in demand all over the United States and that he is promoting in the right way; but he considers the campaign as only commencing and he is urgent that unless the "sinews of war" are forthcoming, the company must collapse and the effect of what has already been done, be in a great measure lost. In other words, Mr. Elwood May, though he has done wonders hitherto in advertising, does not see how his business is to be continued and extended without certain continuous expenditure, and his American friends, I gather, are not prepared to spend more, unless they are backed up by English friends and Ceylon planters. His mission to England this time seems to be to raise additional capital for the company, or to intimate plainly that otherwise it may have to disappear and the advertising contracts be closed. This is disappointing news, the more especially as we cannot consider the present a favourable time to appeal to English (albeit tea) capitalists for money, or to Ceylon planters just as they are doing their best for Chicago. So I intimated to Mr. May, adding the hope that a profitable trade must surely be already springing up and that the Exhibition should be a great help to the

success of the company. Mr. May's answer was that we had but a faint idea of the conservative character of the large distributors of established products in America—how that large tea benefactors in New York would not as yet consent even to hold Ceylon tea, as a thing unknown to their customers, and how only by convincing consumers and creating a demand could a stable foundation be laid for a steady, growing trade in Ceylon tea throughout the States. Even the Chicago Exhibition will not do permanent good, unless plans are promoted in a way which Mr. May is prepared to lay before Mr. Grinlinton. "It is a very easy matter," added Mr. May, "to create a temporary trade—to get obliging small tea dealers throughout the country to take off a large quantity of a new tea, once in a way,—each taking a few chests to oblige a commercial traveller it may be. But as such tea would lie on their shelves without demand, the large trade forced in any one year would merely act as a deterrent to any legitimate business extending afterwards, since dealers would never touch the article again." There is something in this argument, and in the strong liking of Yankees for what they are accustomed to, Japanese and Chinese green teas; but I ventured to point out that surely in the Western and Middle States with so large a proportion of "fresh blood,"—of English, Scotch and Irish accustomed to good tea at home—there should be no difficulty in getting them to try Ceylon tea. Nevertheless, Mr. May insists the process must be a slow one, only to be worked out on the lines he has laid down, and which he—still a comparatively young man occupying a position of influence and reputation in New York—is prepared to follow and develop, provided he is adequately supported. Otherwise, apparently, it is a matter of indifference to him personally, whether his past labours are to bring any return to him or not. I have tried to reflect the outcome of our interview; and I could not help regretting that Mr. May had not made his way some months ago to Ceylon, to meet the planting leaders themselves and to lay before them his ideas as what can, and cannot, be done for Ceylon tea in America.

Meantime he and Mr. Grinlinton have seen a good deal of each other, and though "the Commissioner" and Mr. Stretch, who were present, said little at the conversation referred to, I am aware that Mr. May's views as to the Exhibition and Ceylon tea have been adequately explained; but whether they can be accepted is another thing. Some of us interested in Ceylon rather thought that in nominating Mr. Grinlinton as their representative the Planters' Association were arranging for the "Ceylon-American Company" to take the lead at Chicago; but I can see that there may be points of difference of some importance. Of this, however, we may be certain that the Commissioner will allow nothing to interfere with his doing the very best in his judgment for the promotion of Ceylon teas. We shall know more shortly; for Mr. Grinlinton has asked Mr. Leake to call a meeting of the Tea Committee of the London Association to lay his plans, so far as formed, before them, and possibly Mr. Elwood May may have his "say" at the same time. Mr. Grinlinton has already been busy at the Society of Arts, the Colonial Office, &c. His health is improved; but he had evidently had a "shake" and is by no means the man he was when I saw him last in Ceylon, and I ventured to warn him to be especially careful in this treacherous climate against the risk of a relapse from cold of the influenza or its after-effects.—I was glad to learn from him that he does

not see why 80 or 85 million lb. tea should not be shipped this year from Ceylon—he should have said so in the Chamber of Commerce—a quantity which certainly would do as good in the end as all the sooner putting an efficient check on the China trade. However, the actual exports for the first quarter do not point to such large figures, though we may see a steady advance in the remaining quarters.—Mr. May is very strong on the point of keeping up the quality of Ceylon tea if the taste of Americans is to be captured. Here is a complimentary paragraph from a letter to me of a gentleman connected with the Society of Arts:—

"You Ceylon people are putting the Indian tea wallas to shame in respect to Chicago. Your Commissioner, Mr. Grinlinton, was at the Society of Arts the other day. I understand that he is going or has gone to the States as Secretary of the Indian Committee of the Exhibition. I am doing my best to stir up our Indian fellows and I hope we shall not be entirely left out in the cold."

In another direction, very satisfactory progress is reported: Mr. Whittall, who lately referred to the fact that Ceylon tea was evidently becoming better known in America, tells me that RUSSIAN DEALERS are beginning to give special attention to our teas, and that large purchases have lately been made. The great drawback is the want of big breaks; but this is gradually being overcome, and it will no doubt become an object in the larger factories in our higher districts to prepare and send home large breaks of fine teas with the view of meeting the demand for RUSSIA. To get a hold of the Russian tea market would be almost a greater advantage to the Ceylon tea planters than to capture America, though it is best and wisest to fight for both, and for those of Austria, Germany, &c., as well. But have the Ceylon Tea Fund Committee or the Planters' Association done anything towards urging the Java tea planters to turn their attention to the conversion of their own countrymen in Holland as well as the Belgians and West Germans? Java teas are coming in increasing quantities to Mitcing Lane. They ought properly *all* to go to Amsterdam. I must see Mr. Ercest Tye of the Indian Association on this point.

CEYLON TEA COMPANIES.

You have possibly received the report of the "Standard Tea Company of Ceylon" by last mail; but in case not, I send you the copy Mr. Brooke, of Messrs. James Hadden & Co., was good enough to send me:—

THE STANDARD TEA COMPANY OF CEYLON, (LIMITED).

Directors: Alex. Brooke, Esq., 25, Fenchurch Street, London; Peter Meir, Esq., East Grinstead, Sussex; Robt. Kay Shuttleworth, Esq., Wood End, Clitheroe, Lancashire.

Secretary: A. Trafford Brooke.
Agents in Ceylon: Messrs. George Stewart & Co., Colombo.

The Directors submit Statement of Accounts to 31st December, 1891.

The Profit and Loss Account shows a profit on the working of the St. Leonard's Estate (for the ten months from 1st March, from which date it was bought) £1,670 7s 9d.

The results compare favourably with the promises in the Prospectus.

On taking over the Estate there was due to the Vendor, and there has been paid as interest £345 17s 8d.

It is proposed to pay a dividend for the 4½ months of 1891, at the rate of 10 per cent. per annum, free of Income Tax, absorbing £653 13s 11d.

The Eskdale and Liddesdale Estates, bought from Mr. Norman W. Grieve, are taken over as from 1st January, 1892, and promise to be valuable properties.

BALANCE SHEET AT 31ST DECEMBER 1891.

Dr.

Another engagement prevented my being at the meeting which, with so satisfactory a report, was naturally a very pleasant one. Mr. C. H. Hadden, whom I had the pleasure of seeing a few days before, looking as hearty as he has done any time these twenty years back, and Mr. Peter Moir were present and could not help interchanging congratulations on their continued good health. Mr. T. S. Grigson of Messrs. Geo. Stewart & Co. was naturally gratified over the success of the company he had promoted. [Mr. Grigson is returning to Colombo early in May with Mrs. Grigson and children.] Mr. Norman Grieve was elected a Director, and a better one there could not be among Ceylon proprietors; and in this connection Mr. Brooke mentioned to me how "Kandapolla" mark in spite of a falling market had got a higher average for its teas—a fact noteworthy in view of recent adverse criticism on the latest Ceylon Tea Company. This reminded me that the *Echo City* Editor had not dealt fairly with the few notes I left on his desk in correction of his criticism of the "Baring" Company. I referred to the high reputation of the Directors and to the fact that Wangie-oya is a plantation any company might be proud to have; but this part is ignored and only one item accepted and dealt with (1) as follows:—

CEYLON AND ORIENTAL ESTATES COMPANY.

With regard to our criticism of the Ceylon and Orient Estate Company, formed to purchase various tea properties belonging to Messrs. Baring Brothers and Mr. Thring in Ceylon, Mr. Ferguson calls attention to the fact that "the price of tea was abnormally high in March, 1891, and that the comparison made with the question of March, 1892, is therefore hardly a fair one." As we have not the least wish to be unfair in the matter, we are pleased to give prominence to this opinion.

Although we have no doubt as to the correctness of Mr. Ferguson's remark, the fact does not remove the great objection we take to the prospectus on behalf of the public. Why was not the price of tea given? If abnormally high in March, 1891, why could not this fact have been stated? In dealing with the price of tea, we naturally made a comparison between quotations now ruling and those of twelve months ago. The falling off in value is more than abnormal, it is startling.

In his excellent paper on Ceylon, read before the Royal Colonial Institute, Mr. Ferguson detailed how the annual export of tea had risen within 15 years from 1,000,000 lb. to 68,000,000 lb.

"while there is the probability of the Colony attaining to an export of 100,000,000 lb. in the course of the next few years." The author of the paper touched very lightly, indeed, upon the decline of the London market. "But on the other hand, the falling prices of recent years for tea generally, and the fear of over-production—of supply out-running a demand profitable to the planter—forbids me to say that there is scope in Ceylon for more tea-planters, unless they be young men with capital." To show what an important part the market price of a product plays in the finances of those who grow it we have only to recall the collapse of cinchona, or Peruvian bark, which at one time was being planted all over semi-abandoned coffee estates. "Over the hill country generally"—we again quote Mr. Ferguson's words—"this culture has had to be given up, since the price of quinine fell (mainly through large crops of bark from Ceylon) from

12s to 1s AN OUNCE—

and even to 9d an ounce—between the years 1877-79 and 1891." Against the tea enterprise, as a whole, we have not a word to say. No doubt means will always be found, by cheapening of labour and economy of management, to keep a fair margin of profit in all the best districts; but with regard to the company formed for the purchase of Messrs. Baring's estates, we cannot advise our readers to entrust any single one of their financial eggs to so doubtful a basket.

In connection with Tea Companies, I cannot help referring to the sudden death of Mr. DAVID REID, Chairman of the Ceylon Plantations Company, and whose name has been so fully in your columns of late, the contractor for the Nawalapitiya and Mtatale Railways, and the Unionist candidate for Cackmannan and Kinross shires. A career which seemed only to be opening at home, has been thus unexpectedly closed to the great regret of a wide circle of friends. Much sympathy will be felt for Mrs. Reid and family.

I was pleased to see Mr. GEO. HEDGES looking so well on meeting him in the City the other day, and to learn of his hopefulness about the steady development of the Ceylon tea trade with Australasia which he did so much to foster and develop, by his visits to Melbourne, in the early days.

As regards the future and improved preparation of Ceylon tea, I feel sure there is much yet to be heard. Several experiments in this direction have come under my notice of late; in one case the process of fermentation and drying is the subject of close, detailed and scientific observation under the direction of an experienced planter, who, however, does not wish names or operations mentioned further in the meantime. The respective merits of high and low temperature drying will also be

further tested. I have seen a report by a member of Messrs. W. J. & H. Thompson's firm, of a most favourable character on samples of Indian teas, dried at a low temperature. But more light and experiences generally are required.

As to the MANURING OF TEA and an improved AGRICULTURE generally, you are likely to hear from Mr. John Hughes by this, if not indeed, by last mail; for Mr. Hughes has been good enough to write the following to me worthy of quotation even at the risk of repetition, especially what is said of tea:—

By last Friday's mail I forwarded to your office, Colombo, a copy of Dr. Voelcker's lecture on Thursday, April 7th, at the Indian section of the Society of Arts on the Agricultural Needs of India. I also enclosed some remarks of mine upon one of the points raised in reference to the present practice of burning cow-dung cakes or sun-dried *brallies* as they are called.

I pointed out that the practice was no doubt a waste of valuable manure, but being the result of necessity and not of choice the natives could not be blamed, and that the Government should rather endeavour to provide other fuel such as the supply of forest reserves. But after all that in as much as the whole of the mineral salts such as the potash, lime and phosphates remained in the ashes which under proper sanitary arrangements should be restored to the land; the actual loss was confined to the nitrogen compounds, which however being resolved on burning into gaseous products were either absorbed by the growing plant or crops or were brought down again in the rain and to a great extent retained by the soil for subsequent plant food.

As regards the absorption of nitrogen from the air it is important to remember that in round numbers 80 per cent of the atmosphere really consists of nitrogen in a free form. Further recent scientific research has proved that leguminous plants such as vetch, clover, peas, beans, lupinos, &c. have the power in a very special degree of absorbing this nitrogen and yielding large crops of valuable food and also by virtue of increased root extension leaving the soil also richer in plant food for the future crop. What leguminous plants therefore can do in a special degree other plants may be able to do in a smaller degree so that we may find by and by that nitrogen especially in tropical climates is largely supplied to plants and trees by natural means and does not require to be supplied directly by artificial means as we find necessary in our temperate climes. How comes it that India has for centuries produced crops of corn, rice, gram, &c., without practically any nitrogenous manure being supplied, and yet the soil appears no more exhausted now than at the commencement?

It would be a most interesting experiment if a Ceylon planter would select a good average tea bush just ready for pruning and pick off all the leaves, weigh them at once and then dry them gradually in the sun like grass is made into hay, then again weigh the dried leaves and forward a sample here for analysis.

We should then know the actual weight of the green leaf per acre and with the weight of the dried leaf could make a calculation of the water lost. I believe we should find the quantity of nitrogen very large and much in excess of the supply of the soil itself.

THE KELANI VALLEY TEA ASSOCIATION, LIMITED.

REPORT OF THE BOARD OF DIRECTORS.

To be presented to the Shareholders at their Sixth Annual Ordinary Meeting, to be held at the Offices of the Company, on the 27th April, 1892, at 2-30 p.m.

The Directors beg herewith to submit to the Shareholders the Report and Accounts of the Company for 1891.

The results of the year have been somewhat affected by the low prices of tea obtained, giving for the Company's produce a loss average than for previous

year. Still, the Board consider the Profit and Loss Account a satisfactory one, especially in view of the acreage in full bearing being still so small, the production being over 462 lb. to the acre, the large quantity of tea made somewhat compensating for the low prices obtained.

During the past year the Directors have acquired two blocks of native land, referred to in former reports, amounting to 43 aca., 1 rd. 28 pa., of wblob 30 aca have been cleared and planted with tea.

The Company's acreage now consists of the following :-

	acres.
Under tea in full bearing	123
1887 Clearing	220
1888 "	217
1889 "	10
1890 "	34
1891 "	30½
Acreage under tea	634½
Grass	3
Jungle	306½
In all	943½

This acreage includes Dover.

The estimate of tea crop for 1891 was 216,700 lb., and the quantity despatched from estate 263,497 lb., showing an excess over estimate of 46,797 lb.

During the year 303 aca have been cleared and planted with tea, and the prospects from this addition are very favourable.

It will be seen that a further substantial sum has been expended on our factory and machinery, and for dam, &c. Some further small additions will be required to the machinery in 1892, but practically, our capital expenditure under this head has ceased for the present.

The whole of the last issue of 397 shares, at £1 premium, has been allotted, and the Directors think it a suitable opportunity to commence a Reserve Fund, and propose to appropriate the premiums on these, and on a former allotment of shares to that purpose. The amount of £954 10s is already invested in Consols in the names of the Chairman and Secretary.

The net profits shown in the Company's Profit and Loss Account, including balance brought forward, are £1,688 6 9 which it is proposed to apportion as follows:-

An interim dividend at 2½ per cent paid in Oct. 1891, absorbed	£240 15 0
It is now proposed to pay a final dividend of 7½ per. free of	
In come Tax (making 10 per cent for the year) absorbing	755 11 0
And to place to Reserve Fund, as explained above	654 10 0
	1,659 16 0

Leaving a balance to carry forward of £28 10 9

TIMBER, FUEL AND FOREST
PRODUCE IN UVA.

From a notice under the Forest Ordinance which has appeared in the *Gazette* showing the rates of royalty on various enumerated timbers in Uva, we should judge that this Province of low and high altitudes and warm and cool climates must grow altogether or very nearly every forest tree indigenous to or naturalized in Ceylon, low country and high. We have :-

At a special rate	1
First class	4
Second class	31
Third class	32
Fourth class	59

Total .. 127

The wood specially rated is ebony; the four placed in the first class at R1 per cubic foot are: hal-millilla, nedum, satinwood, and tamarind. Amongst the 31 in the second class at 50 cents per cubic foot, we find doon and hill-doon, hulanhik, jak and kina, na (iron-wood) and palu, sapu, euriya, suriyamara, wa and wahnruu. This last is generally known as wild or jungle satinwood. We are somewhat surprised to find this wood and sapu ranked second class. Of the 32 third class timbers at 30 cents, the most notable are damba, del and waverana. There are also domba and dombakina. Amongst the fourth class trees valued at only 15 cents per cubic foot is the very tree which gave its name to the capital of Uva—badulla. In succession we get bombi, bomhoo, bol "Emberella" must, of course, be a corruption of the word "umbrella," itself connected with umbrageous? In this category there is a wal-kina, but who is responsible for spelling the nelli tree "Nelly"? Ravan-gedilla must convey a reminiscence of the mythical arch-demon of Ceylon, represented as a monster of wickedness, and yet for the slaying of whom a god of the Hindu pantheon was subjected to severe penance! Rikattana and Rukattana look as if some tree-namer has been amusing himself. In this list there is a wal-jambu, one of the *eugenas*, of course, but what its affinity to the cultivated jamun may be we do not know. But we do know that but a percentage of the 127 timbers enumerated in the Uva list are used by the native carpenters, who are, like all orientalis, very conservative. In the rates for sawn timber we notice that no "Upcountry woods" are in the first class, and a note to "Upcountry woods" states: "25 per cent extra charged for milla, jak and knmbuk." Our planting readers will be specially interested in the rates charged for shingles, round timber, fuel-wood, charcoal, bambus and mana grass. We quote as follows:—

SHINGLES.

R15 to R20⁰ per 1,000 delivered at the Haputale Depot.

SCHEDULE OF RATES OF MINOR FOREST PRODUCE.
Charcoal.

Delivered at Badulla Depot, per bushel	0 33
Do Haputale Depot, per bushel	0 30
If burnt by parties in the forest under supervision, royalty per bushel ..	0 10
Bamboos and Canos.	
Royalty on canes per 1,000 6 feet in length	5 0
Do rattans per 1,000	4 0
Do bamboo creepers per 1,000 12 feet long	3 0
Illuk and Mana Grass, &c.	
To estates for a permit to cut and remove for 6 months.. .. .	2 50
To public departments and private purchasers other than villagers, per 1,000 bundles, 2 feet in circumference	2 0
To villagers for their <i>bona fide</i> use	Free
Permits to collect Bin-kohomba, per cwt.	2 6

Bricks and tiles made from materials obtained from Crown forests, at 50 cents per 1,000. All rights to collect gallnuts, birds' nests, &c., to be sold yearly. What is "Bin-kohomba"? The "birds' nests," for the right of collecting which payment is demanded, are, of course, the glutinous nests of the cave-haunting swiftlets, and which the Chinese prize highly for soap-making purposes, as they do the sea-slugs found along our coasts.

THE EASTERN PRODUCE AND ESTATES COMPANY, LIMITED.

Report to be presented at the fifth Ordinary general meeting, to be held at Winchester House, Old Broad Street, at 12 o'clock noon on the 28th April 1892.

The directors herewith submit report and balance sheet for the year's working, ending December 31st 1891.

The profit for the year, including £4,572 4s 1d, brought forward from the last account, amounts to £26,608 13s 4d, and, after providing for payment of interest on debentures and dividend on the preference shares, there remains a sum of £15,177 15s 10d to be dealt with in terms of the company's articles of association. As the shareholders are aware, provision is there made for the appropriation of profits, after payment of debenture interest and dividend on preference shares:—first for the creation and maintenance of a reserve fund of £10,000 applicable if required for the payment of said interest and dividends; secondly, for the redemption of debentures to the value of £3,000 each year, and thereafter for the payment of a dividend on the ordinary shares, not to exceed the rate of three per cent per annum, until the debentures shall be reduced below £50,000. Any surplus profits after payment of dividend at that rate to be applied in further redemption of debentures.

Having set aside £3,000 as required for payment of debentures out of profits, it is proposed to declare a dividend at the rate of 1½ per cent per annum, free from Income Tax for the year 1891 on the ordinary share capital. There will then remain a balance of 7,690 15s 4d, to be carried forward to next year's accounts.

It will be noted that debenture debt was reduced by £10,010 drawn and paid off in 1891.

As shown in the schedule annexed there are 9,236 acres of the company's property under tea cultivation of which about 6,700 are over four years old. The yield of tea in 1891 amounted to 2,008,000 lb. the average gross price obtained being approximately 93d. per lb. The crop for 1892 is estimated at 2,240,000 lb.

The directors have sold three estates during the past year, viz:—Belgodde, Montefiore and Sinneode Belle Vue, proceeds of sales being carried to the credit of "estates reserve account, realizations and recoveries."

In accordance with the articles of association, two of the directors, viz:—Mr. Norman W. Grieve and Mr. David Reid, retire from office and, being eligible offer themselves for re-election. The retiring auditors, Messrs. Welton Jones & Co., also offer themselves for re-election.

SCHEDULE OF THE COMPANY'S ESTATES AT 31st DECEMBER, 1891.

Arapolakando	Koladenia

			Total.. 16,791

NOTES ON PRODUCE AND FINANCE.

THE BUDGET AND PRODUCE.—In his speech on the Budget, Mr. Goschen made the following reference to tea, coffee, and cocoa:—"Tea has been extremely satisfactory. The receipts from tea were £3,434,000, against an estimate of £3,400,000, and against the receipts last year of £3,412,000. I must say that the result is more satisfactory than it appears, because a considerable amount of duty was paid at the beginning of the last financial year, the tea having been held back in expectation of a reduction in duty. That amount can be pretty well calculated, and the real increase on tea is £150,000, representing an increase of 4½ per cent. Of that 2 per cent. will be due to the increase in population and the fact of there being extra days in the year; but the remaining 2½ per cent. is a *bona fide* increase in consumption. The Coffee Group produces £331,000, or £2,000 loss than the estimates. But where coffee shows a slight decrease cocoa shows a slight increase."

MINING LANE AND ITS MERCHANTS.—In the *Daily Graphic* of Tuesday there is a sketch of the Indian tea sale room in Mining Lane during the progress of a sale. Underneath the sketch which is referred to as "A Pulse of the Nation's Prosperity—The Headquarters of the Tea Trade of the London Commercial Sale Room, Mining Lane," there is a quotation from Mr. Goschen's remarks about the increased consumption of tea in his Budget speech. Under the heading "The Cup That Cheers," our contemporary says:—"On June 1st, 1811, the narrow little thoroughfare known as Mining Lane was in a state of considerable excitement, for the Lord Mayor was coming in state to lay the foundation of the London Commercial Sale Rooms, accompanied by the 'band of the Honourable East India Company.' The ceremony was duly performed, and as the official report states, the Lord Mayor, 'having received a bottle of rum as a British colonial production broke the same upon the stone, and afterwards a bottle of wine, the produce of Portugal, the brave and faithful ally of Great Britain, and pronounced

the name of the institution to be the 'London Commercial Sale Rooms.' Such exertions necessitated refreshments, and the party forthwith proceeded to an 'elegant cold collation,' where his lordship, in a burst of eloquence, said 'the tyrant of Europe east unceasingly an envious eye upon this happy island, and longed, but would long in vain, for her ships, her colonies, and her commerce.' Launched under such august auspices it might have been hoped that a grateful Mining Lane would desert its coffee-houses and other miscellaneous places of business, and crowd the 'subscription room,' the numerous sale rooms, and the reading room. But merchants and brokers of those, as of the present days, were conservative in their habits, and for many years the London Commercial Sale Rooms were called, after their chief promoter, 'Martin's Folly,' and the shares dwindled in price from par to £17 per cent. As trade developed, and new articles were included in the comprehensive lists of Mining Lane, the advantages of the rooms were, however, gradually recognised, and today there are 1,500 subscribers to the institution, which is so much too small for their requirements that it is to be pulled down, and a more commodious building erected. Like many other great ideas, the Commercial Sale Rooms were started before their time; but time has amply justified the enterprise of Mr. Martin, who, by the way was one of the founders of the firm of Hollams, Son and Coward, the well-known commercial solicitors. Mining Lane as a thoroughfare is certainly insignificant and uninteresting, but Mining Lane, in regard to the commercial interests located within its dingy offices, or the vast 'warens' which front upon it, is one of the most important centres of commercial London. Here are located, for instance, the great sugar merchants and brokers, and a trade of vast extent is transacted in this article alone—not as formerly in sugar mostly of colonial growth, but now principally in beetroot and the crystallised goods heavily subsidised by foreign governments for the benefit of British consumers. Even more important, perhaps, than the sugar is the tea trade, an essentially British, nay, an almost exclusively London industry. This business is divided into the Indian and Ceylon and the China trades, and these have each their separate dealers and sale rooms."

TEA-PLANTING AND PHILANTHROPY.—In the current number of *Scribner* there is an article on the "Social Awakening of London," in which reference is made to the work done in the East-end by P. R. Buchanan. The writer says:—"The University Club has the constant support of Mr. Buchanan, who lives in B. Thel Green with his family for the sake of entering into an intimate, helpful relation with working people." Of the teetotal clubs founded by Mr. Buchanan the writer says:—"These unique institutions are the creation of Mr. Buchanan. They combine the features of a coffee-house supplying a variety of good food and non-alcoholic drinks with those of a club having numerous facilities for improvement and recreation. Mr. Buchanan illustrates" says the writer, "the new type of man now coming forward in England, who with intelligence, means, and energy shall devote himself and his possessions to working out plans for widening the circuit of life for the toiling majority of his fellow-countrymen."

CEYLON TEA IN AMERICA.—Mr. S. Elwood May, President of the Ceylon Planters' Tea Company of New York, arrived in London a few days since, and is now staying temporarily at the Hotel Victoria. The Ceylon Planters' Tea Company of New York was established for the purpose of introducing and promoting the sale, in the United States and Canada, of pure Ceylon tea; and Mr. Elwood May's visit to this country has been undertaken chiefly with the object of furthering the operations of the company by consultation in the first place with the members of the Ceylon Association in London.

LAST WEEK TEA MARKET.—Discussing last week's tea market, the *Produce Markets' Review* says:—"Indian tea has been more freely offered, including a fairly good assortment of medium and fine grades. These have been actively dealt in at firm

to advancing prices, the market again closing strong with a tendency to a further upward movement. The liberal supplies of Ceylon tea now coming forward, which were expected to check the advance in Indian growths, have so far had no effect, and it appears probable, with a further curtailment of good Indian grades, which is almost certain to take place later on, the rise established will be increased. For the common descriptions the demand has slightly improved, but the quantity placed on the market has been amply sufficient to meet the enquiry, and consequently prices have been barely maintained. The deliveries for the past month were unusually large, as will be seen by the figures below, but, owing to larger imports, the surplus stock has not been materially reduced, and is still about 6,000,000 lb. in excess of the preceding year, although only about 3,000,000 lb. larger than in 1890. The demand for Indian tea for other markets is steadily increasing, but the rate of progress is not sufficient to relieve this market of the additional supplies promised in the coming ensuing seasons. It is understood, however, that greater efforts will be made to produce tea that will more effectively meet the requirements of an export demand. There are two important things to be considered, especially for the development of the export demand from America and Canada, namely, the size of the leaf and of the packages. The former should correspond as nearly as possible with the leaf of China Congou, and a good proportion of the tea should be packed in half-chests, containing about sixty pounds. There is little change of any kind in the position of Ceylon teas. A fair quantity has been offered, but the indifference of the dealers to go further into stock has been about balanced by the apparent willingness of brokers to buy over, and consequently there is no quotable change on values. The quality of the teas has been fairly maintained, as the present standard now goes, but it is seldom, if ever, possible to match the thick juicy teas which were the rule rather than the exception two seasons ago. The imports for the month were only 710,026 lb. in excess of last year's, but the stock still stands at a rather high figure, namely, 16,686,854 lb., as against 11,779,720 lb. on March 31, 1891. The exports from Colombo, according to the latest advices, dated March 7, were 11,239,061 lb., or nearly 1,000,000 lb. in excess of last year."

ANOTHER COFFEE SUBSTITUTE.—According to a German paper the fruit of the wax palm (*Corypha cerifera, L.*) is being used in Brazil as a coffee substitute. The fruit of this tree is of a stony consistency, which, however, disappears during the roasting process to which it is subjected for the purpose of manufacturing it into "coffee." The following figures show the constitution of the Brazilian fruit before and after roasting:—

	Ornde fruit. per cent.	Roasted fruit. per cent.
Water ...	9.87	3.76
Albuminoids ...	5.82	6.14
Fat ...	10.57	14.06
Sugar and dextrine	1.67	1.25
Starch ...	2.47	5.46
Other non-nitrogenous extract substances	23.01	27.79
Woody fibre ...	44.31	38.45
Ash ...	2.06	2.24
Substances soluble in water ...	12.17	13.50

—*H. and C. Mail*, April 15.

INDIAN TEA AND THE CHICAGO EXHIBITION.—We learn that the subscriptions to the proposed Tea Fund in support of the above, and other opportunities for pushing Indian tea, are coming in satisfactorily, although somewhat slowly. It is hoped that the response to the circular we published last week will be general, as it is only in that way that the effort can be successful. The Government of India, we believe, are prepared to follow the example of the Ceylon Government, and subsidize the planters' efforts. The appointment of a special commissioner direct from Calcutta, approved of by the Government

of India, who would take charge of the arrangements, would be generally welcomed. The sooner this is done the better, as we understand that Mr. Griulinton, the commissioner deputed by the Ceylon people and their Government, has already reached London en route to Chicago.

THE SILVER QUESTION.—It was very unlikely that Sir Frank Adam's views on the silver question, as expressed at the recent meeting of the East India Association, would meet with general approval in India. We notice that the *Bombay Gazette* invites those who believe that the finances and the export and import trade of India may with advantage be left dependent upon "the whims and intrigues of Washington politicians" to take into account the contingency of the United States suspending their purchases of silver, and remarks that the complacency with which Sir Frank Adam declares that the loss due to the decline in exchange is temporary, falls only on individuals, and is actually very small, is worthy rather of the doctrinaire than "practical man of business." The serious fall in the gold price of silver has gone too far to please even those who at one time believed that the low price of silver was a splendid stimulus to trade, although planters have very little fault to find with the position. From Bengal we learn that it is difficult to remember when the exchange question so earnestly engrossed attention as it has done of late. Any rapid drop unrelieved by a partial recovery has always tended to disorganise trade in every direction, and this is the more marked now when each disappearing thirty-second means a larger percentage than when we were higher up in the scale. The effect of the fall in silver, and the constant and violent fluctuations in price upon the Eastern banks is shown very clearly in the statement made by the chairman of the Chartered Mercantile Bank of India, London, and China, at the meeting on Tuesday. The credit balance is only £18,279, or rather under 2½ per cent. upon the capital. The directors have decided to carry this amount forward to the next half-year—a prudent course. As it is not put to reserve, it is still available for dividend at any future time. The shrinkage in the bank's business is shown by the fact that the cash and bullion amounts to £2,100,000, and securities freely convertible into cash are put at about another million. If, as the chairman said, trade were good, and credit generally established, the bulk of that money would be in circulation and making profit for the bank.

NO CAUSE FOR COMPLAINT.—But it is an ill wind that blows no one any good. Planters, as a rule, have no objection to the low price of silver. Speaking at the annual meeting of the Standard Tea Company of Ceylon, reported in another column, the chairman, Mr. Alex. Brooke, said:—"Exchange is favourable to planters, and seems likely to continue so for awhile—at least, if there be no Government tinkering with silver." Thus, what is a matter of general distress to many members of the Eastern communities is a boon to employers of labour, who pay in silver and realise in sterling on this side.

LAST WEEK'S TEA SALES.—Of last week's tea sales the *Grocer* says:—"The only public sales of Indian tea held this week were on Monday last, when, preparatory to the market closing for the Easter holidays, no less than 13,580 packages were offered, which met a reception similar to that accorded these descriptions of teas for many weeks past, that is to say, while the small proportion of what may be called fine qualities with strength were readily taken at firm rates, the remainder, consisting of poorer and commoner sorts found a dragging demand at cheap and here and there at 1d. to 1½d. per lb. lower prices. Calcutta advices, dated March 23rd, inform us that "the tea season is now over, and the market closed." In London the only arrivals this week have been the "Pindari," with 24,900 lb., and the "Coromandel," with 65,340 lb. Nearly 14,000 packages of Ceylon tea have been offered, and the market still retains a quiet tone. There has been little disposition to carry stock over the holidays, which has tended to depress prices. Sales have been on a liberal scale since Christmas, and the trade will be heartily glad of a short interval of rest.—*H. and C. Mail*, April 22nd.

TEA GROWING IN ENGLAND.

"J. R." writes from London to a local contemporary:—

I have lately been selling tea plants raised in this country from imported seed. When I first saw those tea plants, I was much struck with their fine and healthy appearance. They have been so carefully reared by Mr. Seaton and gradually hardened at his nurseries at Roehampton that I can quite believe what one man told me—that he had been trying experiments with the single specimen which he has, and had often put in outside his window in town on some of the coldest days last winter and it *would not kill*. It certainly looked very far from being killed, or of having anything the matter with it when he showed it to me. The tops of three of the plants were cut off last August, and put into a pot and forced, and the result, which was shown to me in February, was a splendid show of leaf, and a really beautiful lot of blossom. I heard of a tea bush some years old at Kew; so went down there. I was disappointed to find it had been allowed to grow almost wild, the result being a wooping-willow-sort of tree some six or seven feet high, giving no entirely erroneous impression of a tea bush in bearing, there being not a sign of flush on it. The British public naturally conclude, as indeed the man at Kew thought who showed it to me, that tea is made from the ordinary leaf with which the tree is covered. I wrote the directors of the Royal Gardens offering to go down and to prune this tree, and said that, if they would put it into a hotter house, I was certain I could make some tea from it very soon. I had a courteous reply from your old friend, Mr. Morris, the assistant director, but he said they were afraid to risk any experiments with their tea tree, as it was the only one they had.

Having once got the idea of making some tea in this country from English-grown leaf, I went out to Mr. Seaton's nurseries at Roehampton again, and made a selection of some of the plants for special treatment. I have not had much of a flush yet, but from young "bangy" leaf and some tips have produced an article which has been reported on not unfavourably by tea experts. It is not easy to manipulate such a very small quantity, and such leaf as I have yet been able to pluck will scarcely roll properly or ferment. My samples passed muster, however, amongst a lot of six or eight, and I hope very soon to produce a sample which I shall not be afraid to put along with anything you are sending home just now, and I am very sure your "tuppenny" will not be in it! I am curious to know if anyone else has ever tried tea-making in this country from tea grown here; perhaps some of your readers can give me information as to this. It would not, of course, pay to grow tea in this country, and it can never be produced here at 3d a pound. My first pound will have cost quite a fabulous sum, and I doubt if it would pay to sell it at even the fancy price put on the pound or two of tips which made such a noise last year; still, the first pound of tea made in this country from leaf grown in England, say in London, would not be without its own value, and would certainly be of interest to many.

As I pointed out in a letter to the *St. James's Gazette* lately, referring to an article on Indian and Ceylon vs. China teas which had appeared in that journal, it is a curious fact that, in 1830, when I opened a 100 acre clearing for tea in the Kelani Valley, and advertised for plants, I could not get any at any price, and had to put out seed at stake, while this year I am advertising tea plants for sale in London, and many grocers and tea-dealers have those plants now growing in their shop-windows all over the country. They make a popular and attractive advertisement in the window or on the counter, and there is evidently an increasing demand for them, as I have had applications for dozens, for hundreds, and even for a thousand of them at a time, and for seedlings and seed by the thousand. If this sort of things goes on, I suppose, we shall soon be able

to buy Ceylon tea at a penny a pound as good as we pay a penny an ounce for now. Who would not with such prospects, be a tea planter! All the same I would say: make hay while the sun shines, and keep your name up for quality. Do not try to compete in cheapness or in low prices, and give up sending home "tuppenny teas."

STANDARD TEA COMPANY OF CEYLON LIMITED.

The first annual meeting of this company was held at the offices, 25, Fenchurch Street, on April 12. The directors present were:—Mr. Alex. Brooke in the chair, Mr. Peter Moir, and Mr. Robert Kay Shuttleworth. The shareholders present included the following names: well known in Ceylon:—Messrs. Thomas S. Grigson, Norman W. Grieve George Johnston, and J. L. Austruther.

After the usual formalities, the Chairman said that the report was pretty well confused and had reference almost entirely to the working of the one estate—St. Leonard's, the company's first purchase; that the shareholders were aware that, in addition they now owned the Eskdale and Liddesdale estates of some 1,065 acres in the same district Udupulawa, and within such a distance as to be workable together; but that these were only taken over as from January 1st, 1892; and the report and accounts dealt with the company's existence to December 31st 1891. The results to that date compared favourably with the promises in the prospectus. The quantities of coffee, clove, and tea accounted for to the company, in each case well exceeded the estimates of the prospectus. The general result of the crop 1891 had been a net profit of £1,670 7s 9d. The company bought the St. Leonard's estate as from March 1st, 1891. It was one of the conditions of purchase that they had the benefit of the crop from that date; but, as they were not in a condition to pay for the plant immediately, they had to pay interest, which, at 5 per cent., amounted to £345 17s 8d. Out of the balance the directors proposed that a dividend should be paid for the four and a-half months of 1891 at the rate of 10 per cent. per annum on the first issue of shares, absorbing £658 13s 11d., and that the balance, after paying some small sum to them, the directors, towards expenses and trouble in forming the company, should be carried forward—say something over £600; for it was early days for the company yet and the bulk of the income for 1891 was from coffee, now a somewhat speculative source of income, even in the most favoured districts. The company's tea is still young, and in these high districts it takes longer to come into maturity than in the low countries. The two new estates, Eskdale and Liddesdale, give great promise for tea, both in quantity and quality. At present the leaf is cured on neighbouring estates; but a good factory is being built on St. Leonard's, designed when completed to manufacture as much leaf as is likely to be required. Exchange is favourable for planters at present, and seems likely so to continue, for awhile, at all events, if there be no Government tinkering with silver. The Americans, by legislating to raise the price, so succeeded for a season as to stimulate production to an excess. The inevitable reaction and fall in price followed, until we now see silver lower than we have ever before seen it, viz.: bar silver, London standard, below 39½d per oz. Had they left the article to find its own level, its price ere now probably would have been almost satisfactory to those whose meddling brought about what they now so much deplore; but the rise in price would have been gradual, and much loss saved to many, including a large, hardworking, deserving body—the planters of Ceylon and India. Let us hope that silver will now be left to natural causes, for the planters have natural troubles enough of their own. For the moment, at all events, exchange or silver (for here they are almost synonymous) is in favour of the company, cheapening outlay on the estates, and reducing the cost of factory and coolie lines.

Coolies (our labourers) have to be considered. Good "lines" on Eskdale were nearly complete by last advices. The directors believe in treating coolies well, and that if there be a pressure for labour those estates situated, as the company's are, in a healthy district, and furnished with comfortable "lines," will be greatly advantaged through having the preference before others among coolies. Prices for fine teas, like those from the company's properties, keep up very well, and are about as high as they were a year ago, though the average price of Ceylon tea has fallen. Coffee on St. Leonard's promises to be again a fair crop. It has been estimated at 3,000 bushels for 1892 by Mr. Edward Grigson, who at that figure much under-estimated it last year. There were excessive rains that must have caused some loss in January and February. On Liddesdale, in January, the total fall was 45½ inches in 25 days, against an average of about 70 for the year. We have had no crop figures since; but if there was the same margin on the estimate this year as last year, some coffee may be lost and yet leave a fair crop. Tea from Eskdale also promises exceptionally well; and the general prospects for the year current seemed bright and promising.

Questions were asked about the accounts, and remarks made by Messrs. Johnston, Anstruther, Wilson, and others. When these were answered, the report was adopted. A dividend at the rate of 10 per cent per annum was voted for the four and a half months of 1891, and £50 for division among the directors for past work. Mr. Grieve and Mr. Brooke were respectively elected and re-elected directors, Mr. F. G. M. Grove, A. C. A., auditor.

Mr. Grieve, in returning thanks, said that he had the highest opinion of the estates, of their capabilities, and of their prospects, and that he had backed his opinions in the large amount of shares he held. He added that the chairman had remarked on fine teas keeping up in price, though the average price had fallen. He (Mr. Grieve) might add in confirmation that he had, since he entered the room, a memorandum of prices put into his hands showing that his Eskdale teas were selling that week at 1d per lb. advance in each grade over the prices of the corresponding date last year.

A vote of thanks to the chairman concluded the proceedings.—*H. and C. Mail*, April 22nd.

THE INFLUENCE OF FORESTS ON WATER-SUPPLY.

Does cultivation and protection of forests cause an increase in rainfall? The reply of Mr. Henry Gannett, as published in *Science*, does not tend to confirm the generally admitted opinion on this question; whilst the statistics collected by this scientist have the more value, in that they refer to extended tracts in which the conditions of the country and the climate, both before and after changes in cultural treatment, are perfectly well known.

His observations extend over—

I.—An area of prairie lands in the State of Iowa in the north of Missouri, in the South of Minnesota, Illinois, and partly in Indiana. This area, measuring about 163,000 square miles, was formerly entirely covered with grass, but during the last 30 years large portions of it have been afforested.

II.—The State of Ohio, with an area of about 58,000 square miles, formerly entirely covered with forests of which at the present not one-tenth exists.

III.—An area of about 18,400 square miles situated in Massachusetts, Rhode Island, and Connecticut, which was densely wooded before its colonisation by Europeans. After the almost total destruction of these forests, about one-half of the area has, since 1860, been re-afforested.

If the removal of forests produces a decrease, and afforestation an increase, in the rainfall, the result of observations extending over a long series of years should show in the first instance an increase in the rainfall, in the second a decrease, and in the third a decrease up to 1860, and an increase after that date.

But the statistics collected by Mr. Gannett show that in these prairie lands an increase in the area under forest has not only not been followed by an increase in rainfall, but by an appreciable decrease. In the second instance, that of Ohio, a decrease in rainfall has indeed been proved, but this decrease is so insignificant that it cannot be seriously advanced as a conclusive proof of the unfavorable effect of deforestation. The results of statistics collected in the third instance, that of Massachusetts, also do not tend to confirm in any way the generally accepted theory, for up to 1860 it is shown that there was an evident increase in the rainfall over this area, reaching a maximum of 28 inches annually.

Mr. Gannett also investigated the question as whether the cultivation of land denuded of forest growth resulted in influencing the rainfall; but the result of these investigations proved that no increase or decrease had occurred.

In writing generally on the causes of atmospheric phenomena, we have replied to the often put question which forms the title of this article long before Mr. Gannett wrote on the subject. In this periodical some six years ago we said "that forests do not produce rain, but that they play the important part of storing it up."

As far as concerns Algeria, we have arranged the observations registered at various meteorological stations in the provinces of Oran and Constantine, and these observations, extending over a period of 25 years, refer to large areas covered with forest adjacent to others, which are entirely free from forest growth; and whilst the areas are not to be compared with those reported on by Mr. Gannett, yet the results of the observations are very conclusive.

The region where the rainfall observations have most interest for the forester is bounded on the north, between Bulgaria and Lalala, by the Mediterranean, on the east and west by the valleys of Summam and Sezhonse, and on the south by the high plateaux forming the water-shed between the sea and the desert of Sahara. This tract is in area about 47,000 square miles; and though no regular re-afforestation works are being carried out, yet the closure of large extents of forest and pasture land against the destructive action of the natives may almost be regarded as having a similar effect.

In spite, however, of these protective measures, many thousands of acres have from 1850 to 1875 been burnt over, and it is especially in these burnt areas, when compared with others successfully protected, that the rainfall statistics have the greatest significance.

These statistics show the following results:—

I.—That nearly the same amount of rain fell annually before and after removal of forest growth, and before and after re-afforestation.

II.—That totally different effects are produced by the annual rainfall before and after removal of forest growth, and before and after re-afforestation.

During the summer following the removal of forest growth, the spring level begins to fall, and the following year most of the springs dry up.

In consequence of the water-courses cease to be permanent and become intermittent, being transformed, during actual rainfall, into impetuous torrents, which cease to flow during dry weather.

The valley of Oned-Guehli to the north of the province of Constantine furnishes a remarkable instance of this.

This immense valley is divided into two portions by the river of the same name, and the western side includes the densest forests of this region, whilst the eastern is almost entirely denuded.

During eight years of topographical research in those mountains, we have invariably remarked that during the winter, when heavy rain falls persistently, often for weeks at a time, the floods in the water courses from the Western or wooded side rise slowly, and rarely overflow the banks, and even after tropical rain storms, which are frequent, the water remains clear.

On the eastern or denuded side, however, this is not the case. Scarcely has the rain commenced when each small ravine becomes a torrent, which rolls

down gravel, boulders, and rocks, and overwhelms the neighbouring fields: whilst the muddy water passes rapidly on, arrested by no vegetation, conferring no benefit on the country it traverses,—to leave behind, on the cessation of rain, nothing but dry and rocky ravines.

There is, however, no need to expatiate on the disastrous action of rain in mountains and unwooded countries, it being too well-known.

At the same time, well-informed people have frequently an exaggerated idea of the value of mountain forests, attributing to them other virtues than those which they possess. The virtues they do possess are the power of storing up the rainfall, and thereby regulating the flow of water-courses and springs, and they are entitled to respect.

Our rainfall observations are extremely interesting in reference to forests which have been destroyed by fire: in such forests the annual rainfall remaining unchanged the springs dry up and the water-courses become dry ravines.

We need not be content with contemporaneous evidence; we can also bring valuable witness from the past to the truth of our assertions. About 10 miles to the west of the road from Constantine to Batna there is a horse-shoe shaped mountain range, with its convex towards the east. This range is named Djebel Aouda by the natives of the country. The inner slopes of this horse-shoe were formerly thickly wooded, a fact proved by the presence of stumps of oak trees. These stumps, deeply charred and rooted in soil thoroughly baked by the fire which destroyed the trees themselves have hitherto resisted the decomposing effects of time. An enumeration of the stumps shows a former growth of about 60 large trees per acre, and in the centre of this magnificent forest there are the remains, in brown stone, of a gigantic tank, and issuing therefrom a broad aqueduct, traceable in its ruins for several miles. Today the soil of Djebel Aouda is one of the most arid in Algeria; in former days a strong spring existed, its water-supply stored and protected by a sturdy forest growth.

In concluding this short paper, we would like to add that, though the extent of the areas under our notice cannot compare with those observed by Mr. Gannett, on the other hand our rainfall stations are much closer to each other than those under Mr. Gannett's registration. Of 44 such stations erected by the Government of Algeria, the four which enclose the tract of Oned-Guobli have been most useful to us. It is this tract of country that the observations above recorded refer to, and these observations lead us to the conclusion that "the salutary influence of forests in storing atmospheric humidity is irrefutable; but to enable them to store this humidity, the atmosphere must first contain it.—L. PARQUET in *Revue des Eaux Forêts*.

DUNG V. ARTIFICIAL MANURE.

High-fod manure is more nutritious to the soil than the produce of plain-feeding, but it is questionable whether its extra richness could not be supplied more economically in the form of commercial fertilisers. This is where and how the merits of home-made and artificial manures have come so closely into competition, and what has in many instances led to an extensive substitution of the one for the other. It has to some extent been found that the three main elements—nitrogen, potash, and phosphoric acid—extracted by crops, in kind, at recent market value, be returned to the soil more profitably in the shape of special than general manures. That may be, from such a cause as we have just referred to, but is not the advantage of applying artificial fertilisers, instead of well-rotted dung, more apparent than real?

We repeat that rather more than three times as much nitrogen as phosphoric acid is removed from the soil by crops. Farmyard dung returns these elements in similar proportions, but, of course, it would be a mistake to suppose that dung supplies nitrogen to any crop at the rate of 12 lb. per ton, or anything approaching that quantity. Its duration as a

manure extends over four or five crops, but the close resemblance which its chemical composition bears to that of ordinary crops as regards mineral ingredients points it out as a peculiarly suitable manure for the purpose of maintaining the fertility of regularly cropped soil, while it furnishes much of the material necessary for the promotion of ultrification.

In duration, farmyard manure is excelled only by lime and borax, and this we regard as a very decided point in our favour. We accept the theory that fertility is due to organic residue of previous generations of plants mixed with certain mineral substances of which phosphoric acid and potash are the principal. Organic residue of previous generations of plants is simply another name for farmyard dung. The excrement of cattle, horses, and sheep is nothing more nor less than the indirect residue of plants grown on the farm; and if it is properly managed during the period of fermentation, farmyard manure germinates what for want of a better term, may be called the very essence of fertility.—*Farmer and Stock-Breeder*.

Mr. L. WRAY reports on "gutta ramhong" that it is the rubber from the *Ficus Elasticus*. It is a large, many stemmed-tree, like the banian tree. It is extensively cultivated in Assem. It may be grown from seeds or cuttings. The plants are planted on mounds 3 or 4 feet high, in 40 feet wide cleared lines, through the jungles: the lines being 100 feet apart (the jungle being left standing between them), and the trees placed 25 feet apart along the lines. Beyond once or twice a year clearing the undergrowth round the young trees nothing more requires to be done till the trees are old enough to tap. I do not know how long it is before they begin to yield rubber. There are a few trees near Ipoh, which I think ought to be preserved, as from them seed could be obtained. There are also a few trees in Upper Perak and the Plus. The rubber fetches about \$100 per pikul. From information which has been communicated to the Superintendent of Lower Perak, it appears that both in Langkat and Deli, Sumatra, the natives are successfully opening rembong plantations. The price of young plants is said to be \$1 for a seedling one foot high, and \$2 if two feet or more in height.—*Singapore Free Press*.

MALTESE BLOOD ORANGE.—H. E. Van Deman, pomologist of the department of agriculture at Washington, expresses the following opinion of this orange in the Horticultural Art Journal: "This is one of the choicest and most highly flavored of all the varieties of the orange. It is true that the flavor is not so mild and sweet as some, but in delicate aroma and sprightliness it is scarcely excelled or equalled by any. In size, it is about medium, and in shape it is slightly oval. The peel is not thinner than that of some varieties, but the core is unusually small and seeds are quite rare. The name 'Blood' is attached because of the unusual characteristic red color of the pulp. This, however, varies greatly in different climates; as for instance, in California it is much more inclined to show the red than Florida and the Gulf coast where, in fact, it sometimes occurs that well developed specimens have no red color at all, or but the slightest trace. The skin is also thicker in California, and the flavor is more acid than the same variety grown west of the Mississippi river. In the Mediterranean regions, the flesh is almost as red as that of, the beet, the skin is quite thick and the flavor tart. As its name indicates, this orange is a native, so far back as history goes, of the Island of Malta, in the Mediterranean sea. It has been known there for many centuries, but not before the Christian era, as the Roman writers make no mention of this or any other variety of the orange at that time."—*Rural Californian*.

NOTES FROM OUR LONDON LETTER.

LONDON, April 22.

THE CEYLON TEA PLANTATIONS COMPANY,

we hear that its report has this week been circulated among its shareholders, but no details have yet been allowed to transpire as to the amount of the dividend it recommends. All that has reached me as yet with respect to it is that it contains a suggestion that the Company's chief manager in Ceylon, Mr. G. A. Talbot, who is now in England on leave, shall, during the continuance of that leave, act as as director of the undertaking in place of Mr. Henry Tod. Mr. Reid's death is of course too recent to have enabled arrangements for filling up his place on the same board of directors to have been discussed. Just as my writing had thus far proceeded it became possible for me to learn some of the leading particulars of the report just referred to. It states that the net amount at credit of profit and loss account, including balance brought forward at 31st December 1890, and after providing for general expenses, directors' fees, income tax, &c., was £31,439 3s. 9d. The interim dividend of 7 per cent on the ordinary shares paid 27th October 1891 absorbed £10,254 6s. 0d. It is now proposed to pay a final dividend of 8 per cent on the ordinary shares (making 15 per cent in all, free of income tax) which will absorb a further sum of £11,727 4s. 0d. A dividend on the 7 per cent preference shares was paid on the 30th June 1891, requiring £1,018 3s. 11d. and another similar one paid on the 31st December 1891 took £1,732 13s. 2d. The directors propose to add to the reserve fund out of last year's profits £5,493 8s. 0d. and to carry forward to next year the balance remaining of those amounting to £1,213 8s. 2d. The gross average price realized for the company's teas sold in London during last year was 9½d per lb. this being 1¼d per lb. less than was obtained during the year previous. The report states, however, that the cost of production was one farthing per lb. less than in 1890, so reducing the net difference to 1¼d per lb. This is, however, heavy enough to show how seriously the selling price of tea has been reduced upon the London market, for we believe few groups of estates in Ceylon have sent home teas of more level or better quality than that marked by the Ceylon Plantations Company. Certainly it is a feather in the cap of this large undertaking that in spite of the reduction in price obtained it has yet been able to maintain so satisfactory a dividend as 15 per cent during the past year. All the shareholders are greatly to be congratulated on this result, one which the publication of canonot, but influence opinion as to the remunerativeness of your leading industry. We also strongly feel that, taking that view alone, it must be most satisfactory to the general public in Ceylon that there is now no chance of the Company's continued success being endangered by the undertaking of any enterprise outside of the colony, such as it was proposed to enter in the Straits Settlements. There may as well be added to the particulars above given of this report that the tea received was plucked from 5,000 acres, and that the average yield per acre over this area was 414 lb. per acre. It announces also that all the Company's properties are in excellent condition, and that the factory accommodation and machinery, which were scarcely equal to the requirements of the past year, are now being increased to meet the largely-expanded business of the Company. It is regrettable to observe that this report is signed by the Chairman, the late

Mr. David Reid. Enclosed with it was a circular intimating the death of that gentleman at his residence, Thomases, Kinross-shire, on the 13th inst. I have been obliged to deal with this report in a somewhat unconnected fashion, no copy of it having reached me, and having had to obtain any information respecting it from several different sources, time not having permitted of my amalgamating their intelligence into a more connected form.

GOVERNMENT QUININE.

Under this heading the *Rangoon Times* publishes some interesting remarks anent the Government of India declining to sell sulphate of its own manufacture to anyone beside Government officers. It assumes, among other reasons, that this may be due to Government not wishing to interfere with private trade, in which assumption it is undoubtedly right. Our contemporary proceeds:—"Private vendors of quinine sell it at very high rates, far beyond the reach of very many, and often their article is of inferior quality and greatly adulterated. In the East, where quinine in most places is an absolute necessity to guard against the insidious attacks of the deadly fevers peculiar to the tropics, everyone should be able to get it, and in as pure a state as possible, and no one can for a moment maintain that the Government is competing with private enterprise if it offers an article in the interests of the health and the lives of its subjects, of a purer quality than the article obtainable in the market, and at a rate far below that charged by private vendors. In fact, such a proceeding on the part of Government will have the effect of making private vendors more careful of what they offer the public, and will really give a stimulus to private trade." We concur in the suggestion conveyed in this remark, and would add that there is no reason apparent why Government should not supply local traders with its own manufacture and thus give an impetus to an important industry both in Northern and Southern India.

Dealing with this subject so far as it affects Burma, the *Rangoon Times* continues:—"In Burma, which is preeminently a feverish province, it would be a boon to many engaged in private enterprise in the country to be able to purchase quinine from Government. There are many Europeans, and thousands of Burmans and others, working in the forests for private individuals and firms; large numbers are also employed in exploiting minerals and oil, and many are engaged by private contractors on railway construction and road-making for the Government. The majority of these undertakings is in the most sickly parts of the province, and much inconvenience, and loss is often experienced from the Europeans and the labourers engaged in them falling sick and having to go away from ill health. At the high rate at which private vendors sell their quinine, it would be ruinous to supply everyone who required it with the article and in many cases even it is procurable only in very small quantities. If those engaged in private enterprise were allowed to purchase the Government quinine at the rates at which it is sold to Government officers, a great deal of the sickness which prevails among those engaged on works of public utility and private enterprise in Burma would be avoided, and the province itself would be greatly benefited. It is possible that private individuals can obtain Government quinine by getting it through Government officers, if they are able to show just and sufficient cause why they should be supplied, but such a course is undesirable, on account of the circumlocution which has to be observed, and for several other reasons. We assure the Government of India, that it will be conferring a boon on the people who are intrusted to its care, by making the sale of Government quinine free to everyone, official and non-official alike, at the rates at which it is now sold to Government officers." These arguments are forcible, and will, we trust, receive attention from the Government of India, whose present arrangements for supplying quinine might

easily be improved. We believe we are correct when we state that in Madras planters and private individuals are at liberty to purchase quinine in certain quantities from the Neddiwattam Factory.—*Madras Times*, May 4th.

QUININE AND JAVA CINCHONA.

We publish on page 922 full statistics of the estimated crop of Java cinchona for 1892. The figures have been collected by the Soekaboemi Agricultural Association, that energetic organisation of Java planters to whose efforts on behalf of the cinchona industry we have often had occasion to refer. This is the fourth year of publication of the Association's estimates, which have fairly stood the test of accuracy, although the actual output has always been rather in excess of the forecast. On this occasion, we are told, special pains have been taken to render the figures as correct as possible, and the Association's efforts have been more generally accorded by individual planters than in any previous season. The statistics show that of the 115 plantations known to exist in the island two have been abandoned since last year, while on three others all the trees have been uprooted. Those three plantations only produced an aggregate of 1 0,000 lb. of bark, or less than 3 per cent of the total production—a fact which disposes of the assertion that there has been a general uprooting of trees in consequence of the low prices which have ruled. Moreover, nearly all the uprooted cinchona averaged only 3 to 3½ per cent of quinine sulphate, a yield admittedly too low to hold out any prospect of successful competition in the future. On the other hand, twenty-six plantations have either not yet come into bearing at all or only yield insignificant quantities, while six others, though still in existence and ready to ship bark under more favourable circumstances, did not harvest any last season. These figures indicate that there is plenty of reserve stock in the island to fall back upon when the market improves. Another important feature of the returns is that the quinine value of the bark on almost all the large estates is increasing. The manufacturing bark from Java, which averaged about 3½ cent not long ago, will next season represent an average value of nearly 5 per cent in sulphate of quinine, and that proportion is likely to be still further increased later on. The main interest of the Soekaboemi returns, however, lies in the fact that, for the first time in the history of the Java cinchona industry, they present a falling-off, positive as well as relative, in the shipments from the island. If the unit remains where it is now, the compilers expect the quinine output of the island to be fully 10 per cent less than last season, and even if the unit should improve to 1½d or 1¾d per lb., it is likely to fall below that of 1891 by 1 per cent, or thereabouts. Private advices which have reached us simultaneously with the returns state that the actual shipments will almost certainly fall below the minimum mentioned in the returns, unless, indeed, in the unlikely event of a considerable improvement in prices. What the planters aim in the first place, however, is not so much a considerable advance in the unit value as an assured steadiness in the market, and they will, therefore, endeavour to regulate their shipments in such a manner that the quantities to be offered at the Amsterdam auctions shall be as nearly equal as possible, "experience having proved that the Amsterdam market is an unusually sensitive one, and easily affected by irregularity in the supply."

The position of the Java planters thus resembles that of their Ceylon colleagues in 1886 in this respect—that the excessive forcing of the European bark-market is beginning to produce the inevitable reaction—but the situation is different from that in Ceylon six years ago, first, inasmuch as there is in Java a heavy supply of rich bark to fall back upon; secondly, because the Java growers have taken to heart the lesson that the indiscriminate production of low-grade, quickly-growing bark does not pay; and, finally, because they have not, as the

Ceylon growers had at the time, looming before them the spectre of a new and rapidly growing source of production the advent of which they are bound to forestall at all hazards. There is no important source of supply behind the Java planters. They have taken the lead of the market, and can keep it if they like. That is a fact about which there cannot be two opinions.

The threatened falling-off in the production of Java cinchona-bark would, no doubt, under ordinary circumstances make itself felt in the quinine market. But that market has been hedged to such a degree by speculative sales, that the effect of the laws which usually govern the fluctuations of manufactured products may be retarded for a considerable time. There is certainly no indication yet of any upward movement in quinine, though the signs which would warrant such a tendency are slowly accumulating at the horizon.—*Chemist and Druggist*, April 23rd.

THE CINCHONA ADMINISTRATION REPORT.

The Government of India, in acknowledging receipt of the Annual Report of the Government Cinchona Plantations on the Nilgiris for the year 1890-91, remarked that the quantity of bark in stock at the close of the year amounted to 510,695 lb., which the Director of Plantations (Mr. Lawson) hoped to utilise for the manufacture of quinine during the next few years. The Government of India trusted that these anticipations might be realised, and added:—"It has not been altogether satisfactory that manufacture has failed to keep pace with the increased demand, and the Government of India is glad to observe that the Madras Government is calling for a special Report regarding the alleged inadequacy of the machinery received from England." It also pointed out that one reason for the difficulty experienced in the sale of the quinine powders was probably the high price charged for them, namely, 3 pies each, or at the rate of ₹21 per lb., giving a profit of 50 per cent on the cost of production. It was unable to believe that reluctance existed anywhere in India to take quinine. There was a well-founded repugnance, no doubt, to the cinchona febrifuge on account of its nauseating properties, but no such objection was found to the use of quinine with the effects and potency of which the people were generally familiar. With a view, therefore, to render the retail distribution of quinine successful, the Government of India thought the price should be considerably reduced.

Mr. Lawson, in commenting on the Supreme Government's letter, said that the large amount of bark, in stock consisted chiefly of red bark, which, when compared with crown bark, is poor in quinine; so that to obtain a large amount of quinine it would be necessary to use a much larger quantity than would be the case if it were crown bark. In other words, the amount of bark in stock would not go so far as the number of pounds given in the Report might lead Government to suppose. Of the crown bark remaining, there was ground up a sufficient quantity to last till the end of July next, and of unground bark enough to last till the end of this year. During the next monsoon it is proposed to take a large harvest of crown and crown hybrid bark from the Dodabotta and Naduvattam estates; but although 150,000 lb. have been put down in the Budget Estimate as the probable output, Mr. Lawson will be guided by what is found necessary for the factory, and then after that, by what he thinks desirable to take from the trees. With reference to the remark that the manufacture had failed to keep pace with the increased demand through inadequate machinery, Mr. Lawson said this was not quite the case, as after supplying all requirements there remained at the close of the year 1572 lb. in stock, all of which, and more, had been since intruded for by the various Indian Medical Departments, besides 1,200 lb. of febrifuge. Up to the 31st December, 1891, indents were received which amounted to ₹77,000 or ₹1,000

over the estimated year's expenditure; and after these incidents had all been complied with, there would be still left in stock on the 31st December, 1891, 1,150 lb. of finished quinine and about 100 lb. of unpowdered febrifuge. The machinery at present erected was, he said, adequate to turn out the quinine and febrifuge likely to be indented for; but the machinery in duplicate. Mr. Dawson hoped the Government of India was right in thinking that the native population had no reluctance to taking the quinine; and that the small sale of the powders hitherto was due solely to their high price, which he agreed might be reduced to 2 pies each.

The Surgeon-General with the Government of Madras, to whom the correspondence was forwarded for remarks, said he did not see that any appreciable saving would be effected by sending quinine and jalap in bulk as proposed by the Government of India. On the other hand, it would throw additional work on the subordinates at Municipal hospitals, who had already as much work as they could attend to. Moreover, uniformity in appearance, &c., could only be obtained by adhering to the present system. He did not approve of the suggestion to wrap the powders in old papers, which would increase the possibilities of one powder being mistaken for the other, "moreover, the outer covering of a drug even among more civilised people, has a decided effect on its sale. A recognised feature of the success of proprietary drugs is the neat and attractive way they are made up." To prevent any mistake the wrappers might have printed on them in Tamil "Purgative powder," and "Fever powder," respectively and the outer wrapper enclosing both powders might contain simple directions, such as "the purgative to be taken first and when it has acted, the fever powder." Surgeon-General Fabock's own opinion regarding the sale of these drugs was that it would be in direct ratio to the interest taken in the sale and distribution by Revenue officials. The price of the 5-grain quinine powder has accordingly been fixed by the Madras Government at 2 pies and that of the 100 powder packet at 11, the jalap being issued free of charge as hitherto. This arrangement will give the seller a commission of 3 pies in the rupee or about 4 per cent. as at present. The Madras Government is of opinion that it would be better to continue the existing method of distribution, and it has ordered that the names of the drugs and directions for their use are to be printed on the wrappers in the vernacular of the district to which the packets are sent for distribution.—*N. Mail*, May 5th.

SOURCES OF FERTILITY.

Among the substances produced in the course of the fermentation of dung, organic acids are formed similar, to those found in what is anciently known as humus. These organic acids have a strong affinity for ammonia which they retain firmly in combination. But for this fact, there would doubtless be a much greater loss of ammonia from the manure heap during fermentation than there is, though there is actually more waste every day than should be, by allowing the manual fluid—the very essence of dung—to drain away from the mass.

It is too often forgotten that farmyard dung has something more to command it than its completeness as a manure. Farmers are very apt to look on one side of its usefulness only. Its mechanical virtues are not sufficiently appreciated. It is well known that manuring is not all that the soil requires; its physical condition must be looked after. While dung replenishes the soil with chemical constituents, it also adds bulk and porosity, and thus accelerates drainage. It has, therefore, much to do with the temperature of land. Besides assisting in the removal of superfluous moisture, it renders the soil more absorptive, enabling it to make better use of the heat of the sun than it would otherwise do. This is an extremely important matter.

The temperature of the soil is affected by other causes than the sun's rays. Decaying vegetable matter

is a source of heat, as evidenced by the high temperature generated by the process of fermentation of dung. Farmyard manure thus supplies heat to the soil from two different sources, while it helps it to retain much valuable manurial ingredients, which, in a colder or more purely mineral soil, would be washed away. It also opens up dense, stiff soils to the influences of the air, and gives freer course to the roots of plants. It is not to be commended for application alone, but in conjunction with phosphatic manures we believe that farm-yard dung is indispensable in maintaining the necessary temperature and fertility of the soil.—*Farmer and Stock-Breeder*, April 4th.

CINCHONA-SAMPLING IN AMSTERDAM.

We gave particulars some time ago of a meeting held under the auspices of the Cinchona Warehousing Association in Amsterdam at which it was decided to adopt a new plan of drawing samples of bark. We now understand that the necessary machinery for grinding the bark has been put down, and that the samples for the auction of May 5th, next will be treated upon the new system.—*Chemist and Druggist*.

AGRICULTURAL PRODUCTS OF THE PHILIPPINES.

The United States Consul at Manila says that the principal products of the Philippines are hemp, coffee, rice, tobacco, corn, and fruits. The cultivation of hemp is a very simple operation, and as it yields a large revenue it is not surprising that it is a popular occupation among the people. This staple is the product of a species of planting which grows wild on the Pacific slopes of the volcanic elevations of the Philippine islands, particularly the southern ones. Under cultivation the tree attains a height of 15 or 20 feet, with a trunk from 8 to 12 inches in diameter. In its green state it is crisp and juicy, and can be readily cut down with an ordinary carving knife. The preparation of the hemp for market is very simple. When the tree has properly matured, it is cut down and divided into long strips, which are shredded under a large knife kept in the proper position by a rade lover. This separates the juice and spongy matter from the fibre, and the latter is spread out in the sun to dry, after which it is packed in bales of about 240 lb. for shipment. There are a large number of plantations owned by natives, as well as by Spaniards and mestizos, where the trees are set out in regular rows, and well cared for. The cultivation of the coffee tree has been followed to some extent for the past thirty years, but interest in this branch of cultivation has been renewed during the past four or five years, and it is expected that its export will increase annually. There is no way of ascertaining the area of land occupied by coffee trees nor the amount of coffee annually produced, as the trees are scattered in various parts of the archipelago. The largest plantations are in the province of Batangas, in the island of Luzon, but many of the natives have a few trees in their front yards, under the shade of the plantations, that may yield four or five bushels of coffee berries. The increase in production has been marked within the past few years. In 1897, a little over 5,387 tons were exported; in 1898, about 7,501 tons. Although rice is the native's principal article of food, there is not enough of it produced in the archipelago for local consumption, and more than 70,000 tons are imported annually. The tobacco industry in the Philippines employs a large amount of capital and a vast number of hands. The best tobacco comes from the provinces of Cagayan and Isabella on the island of Luzon, the average annual yield from those being from 60,000 tons to 100,000. Tobacco is also grown in the provinces of North and South Ilocos, Abra, Lepanto, Nueva Ecija, and Union, all on the island of Luzon, and on the islands of Cebu, and Panay. The tobacco produced in the former provinces is called *Igorrotes*, while that from Cebu and Panay is designated *Visayas*. In cultivat-

ing, the earth is well ploughed and harrowed and the seed sown in September. About six weeks later the young plants are transplanted about two feet apart, and the field is kept free from weeds, and otherwise carefully attended to until February, when the plants are almost ripe. The crop is gathered in March and April. It is then made up into "hands" of one hundred leaves each, the leaves of each hand being fastened together at the stem ends with strips of bamboo fibre. These hands are then hung up in rows upon bamboo poles under long sheds, which are open on all sides, and when they are almost dry they are piled up on the ground and allowed to ferment. The leaves are then dried again and packed into bales for shipment to Manila, where they are repacked and pressed into bales for export, or sent to the factories to be converted into cigars and cigarettes. It is not sold by weight at the plantation but by the *fardo*, which contains forty hands. All the tobacco manufactured in the Philippines is made into cigars and cigarettes. The tobacco is classified at the plantation into first, second, third, fourth, fifth, and sixth grades, according to the size and quality of the leaves. In Manila there are twelve large tobacco factories, one of which, La Flor de Isabel, the factory of the Compañia General, manufactures seventy-five brands of cigars, ten brands of cheroots, six grades of cut tobacco, and eight brands of cigarettes. These twelve factories give employment to about 11,000 persons. Besides these there are numerous small factories owned by natives and Chinese. Corn holds a very unimportant place among the agricultural products of the Philippines, although it is cultivated to some extent. All the corn produced is that known as maize or Indian corn. The method of cultivation is similar to that followed in more advanced countries, but the implements used are of a very primitive character. As a rule the land is ploughed with a sharpened stick drawn by a buffalo, after which a heavy wooden frame, about four feet square with long wooden teeth on the under side, is drawn over the ground to break the lumps. The corn is then hoed by hand, and all that is necessary thereafter is to keep the weeds down. No manure nor fertiliser of any kind is used. No attention is given to fruit culture, and mangoes, bananas, apples, guavas and numerous other native fruits grow without cultivation, and are gathered by the natives in the hills and even within the limits of the cities and towns, who bring them to Manila and sell them in the streets and markets. Consul Webb says that no attempt has ever been made to export any of these fruits except a few mangoes, which are sent every year to Hong-Kong and other neighbouring ports, although it is quite probable that under a proper system of cultivation, grafting, &c., some remarkably good fruit might be developed that could be preserved or canned, and sold at a great profit in Europe and the United States.—*Journal of the Society of Arts.*

CALIFORNIAN FRUIT PRODUCTION.

A correspondent, writing to the *Economiste Français* says that at the present time California is one of the principal fruit-producing centres of the world. It is more particularly in the southern part of the State that this industry is the most developed, and Sacramento is the centre of it. It produces all kinds of fruits—pears, peaches, figs, grapes, &c. The pear which is one of the choicest and most easily transportable of fruits, was the first to attract the attention of the grower, and was cultivated on a very considerable scale. The pear tree in California bears at the end of three years, but it is only in full bearing at the end of six or seven. An acre of ground, well planted and carefully attended to, should yield at the expiration of this period about 35,000 lb. weight of fruit, worth £200. Grapes are of three descriptions—those for the table, for wine making, and for drying. Each description has its own special centre of production. Grapes for drying are grown in the valley of San Joaquin, those for wine making, further to the north, and the table fruit is cultivated in the

neighbourhood of Stockton and Sacramento. Southern California is distinguished by very varied climates, which admit of all descriptions of fruit culture. The choicest kind of table grapes are those known as Tokay. A San Francisco paper—the *California*—states that over an area of fifteen acres planted with Tokay grapes, the vines being fourteen years old and well tended, the gross yield was valued at nearly £4,000. Deduction being made of the expense of cultivation, irrigation, transport, and commissions, the net product is estimated at £1,738, that is at the rate of £124 per acre. This, however, is stated to be an exceptional case. After grapes come the figs. These latter are cultivated in very large quantities in California, and there are many different descriptions. An attempt has been made to acclimatise the true Smyrna fig, but it has not hitherto been a success, although fruits have been grown very nearly resembling it but inferior in perfume. The choicest variety and the one most easily obtained is the fig called the "white Adriatic." At Ventura, where it is most successfully cultivated, one grower alone has planted a very large extent of ground, and estimates, judging from past results, that in ten years' time his annual yield will amount to about 1,250 cart loads of fruit, which at the rate of one cent a pound will produce an amount of £50,000. The fruit growers of California having a supply of fruits greater than is necessary for home consumption, are naturally desirous of finding outlets for their supplies, and for some years they have been endeavouring to establish markets on the Atlantic coasts. In the fruit season an exhibition of choice fruits is sent over the principal lines of the Union in a specially constructed wagon, which is called "California on wheels." The cost of this travelling exhibition is borne by the Board of Trade of the State of California and the Southern Pacific Company. At the same time the Board of Trade supports, not without considerable expense, at San Francisco, a permanent exhibition of fresh fruits. The Eastern States, the large cities such as New York, Boston, Philadelphia, and more in the west Chicago, and in the South St. Louis, equally receive regular supplies of fruits. Railways have been constructed to unite the principal producing centres of California with the great transcontinental lines, and to carry the fruits rapidly from one end of the country to the other. But no matter how abundant the yield may be, and the cheapness of transport, fresh fruits are still a luxury, and their sale cannot exhaust the production of California, so for some years now attention has been paid to developing the sale of preserved fruits. At first, these were prepared on the evaporation system, and the fruit was then packed in boxes. This industry has had an enormous development, and the manufacturers of tin boxes in California are considered among the most skilful and the richest in the world. Since 1885 the yield of fruit has been so abundant that the special apparatus for artificial evaporation have been insufficient, and recourse has therefore been had to natural evaporation by solar heat, but the latter system has not given, everywhere, satisfactory results. In the greater part, however, of California, the air is extremely dry, and the desiccation of fruits under the influence of the sun is, says the *Economiste*, absolutely perfect.—*Journal of the Society of Arts.*

THE PEPPERMINT INDUSTRY OF ST. JOSEPH COUNTY, MICHIGAN.*

Next to Wayne county, New York, St. Joseph county in Michigan is the largest peppermint producing locality in the United States. As early as 1846 farmers began to cultivate the plant in this locality and the industry has continued to grow ever since. Most every farmer thereabout now raises some peppermint, but usually in connection with other crops, while a few devote their whole time to its cultivation. By far the principal grower is Mr. Henry

* From the *Pharmaceutical Era*, April 1.

Hall, of Three Rivers, and "Halls Big Marsh of Florence" is the largest piece of land in America devoted to raising peppermint. The farm is eight miles southeast of Three Rivers, and contains some 900 acres, of which 400 acres are put into mint each year and alternated with clover to keep up the strength of the soil. Mr. Hall has four large distilleries with total capacity of some five hundred pounds of oil daily. The largest still house is situated in the centre of a 600 acre field; it contains four stills, and is surrounded with mint fields as far as the eye can see.

The cultivation of the plant is accompanied with more than ordinary care and the success of the crop depends largely upon the attention it receives, as well as the season. The ground is ploughed in August, September, or October, then thoroughly harrowed, and the following spring it must be harrowed again, then marked and planted. Old roots from "first" crop are removed from the ground in spring, and planted in rows three feet apart; a man carries the roots in a sack on his back, throws them into the rows, and they are then "kicked in."

Two or three crops are gathered from each planting, the first and second crops are the best, and twenty pounds of oil to the acre is a good yield; the third crop is very apt to be "weedy" and the yield only about ten pounds to the acre.

From the time the mint appears above the ground until it is gathered, it should be constantly cultivated and hoed to keep it free from weeds, which are the bane of the peppermint grower's existence. The plants mature from the middle of August to the first of September, soon as the blossom is out; the "second" crop mint comes first, then the "first" crop, and lastly the "third." It is cut with a mower and by hand with a scythe, and if weedy the weeds must be stored out by hand. The plant stools out and spreads, but "first" crop is in quite distinct rows; the second year it grows from the runners which fill in the rows making it a more solid mass, and in the "third crop" this is still more apparent.

After cutting, the mint is allowed to partly dry or "cure," and is then raked into cots like hay and drawn to the still house, where it is immediately distilled.

The process of distillation is not complicated but interesting. The still is a large wooden tub with tight hinged top, a steam supply connection at the bottom and outlet to the condenser at the top of one side. The condenser used by Mr. Hall is a very effective and unique piece of apparatus, the worm instead of being in a coil is in longitudinal sections about 14 feet long, which lap under each other, the top about 6 inches in diameter and tapering to some 2 inches at the bottom or outlet, and is made of tin. The cooler consists of a tin trough about 8 inches in diameter with perforated bottom, the length of the condenser, over which it sets, and through the perforations a constant stream of water is kept flowing over the tin condensers.

The mint is drawn to the still house in waggons, pitched into the still, the packer "picks the tub," the top is fastened down and the steam turned on for about an hour or until exhausted; this is told by pulling out a plug in the top of the still. Across the inside bottom of the still is a frame with chain connections that run to the top; by means of a heavy crane, which is connected to these chains, the exhausted mint or "charge" is lifted out of the still and carried away in a waggon. The "mint straw," as it is called, is dried in the sun and used as fodder for sheep and cattle.

The quality of the oil produced depends entirely on the mint used, and the freedom from admixtures of "weeds" or other foreign substances.

Careless and lazy farmers raise poor mints as well as poor wheat, and whether it be "first," "second," or "third" crop mint, thorough cultivation is an important consideration in producing good oil of peppermint. Everything that comes from a still is by no means pure oil, and experience is a most important factor in judging of its quality.

Enough has been written about tests for oil of peppermint to fill a large volume, but one of ex-

perience in the business will judge of the quality of a can of oil almost as soon as he places his nose to the opening. It may be necessary to examine it for water or castor oil and alcohol and possible other adulterants, or to see that none of the menthol has been removed, but the natural flavour of pure oil of peppermint is what the man of experience first seeks.—*Pharmaceutical Journal*.

ANOTHER SUBSTITUTE FOR JUTE.

Wonderful are the uses of the cotton plant! Formerly it was grown for the cotton alone, and the seed was looked upon as a nuisance, to be got rid of in the cheapest way possible, not even being thought worthy of use as a manure, and both it and the hulls were regarded as dangerous food for stock. Now the value of the seed is almost as great as the cotton itself. As an oil producer, a food for stock, and a fertilizer, it is in constant and growing demand, and it has even been suggested that it would pay to develop seed-growth at the expense of the cotton, making that more a secondary product. Up to this time the stalks have retained their old-time valueless character, but this also appears now to be nearing its end, for it is proposed to utilize the fibre contained in them for making bagging. The difficulty in the way has hitherto been the absence of a machine to break them and draw out the fibre. This appears now to be overcome, and another source of profit opened to the cotton-planter, as we learn from the following paragraph, taken from the *Progressive Farmer*:—

"The following from Augusta will be read with interest by all our readers:

"William E. Jackson, a well-known lawyer of this city, has solved the Jute-bagging problem that has agitated cotton circles for so long. Jackson has perfected mechanical appliances for making bagging from cotton stalks, and he has just returned from New York with a roll of bagging.

"Expert cotton men say that it is in every respect equal to jute bagging. He will buy the bare stalks from the farms, and can afford to pay about \$2 a ton laid down. An annual stalk yield will bale three years' cotton crop. The machinery comprises heavy corrugated rollers, with vasts of running water, carding machines, and bagging looms. It is estimated that in making bagging from cotton stalks two million dollars annually will be put into the pockets of farmers for what is now cleared from the fields at an expense.

"Augusta will be headquarters for the company's mill and offices, the demand for the products of which will extend from Virginia to Texas. Jackson had the roll of bagging which is exhibited woven by the jute-bagging looms of J. C. Todd, at Paterson, N. J., and he says that experts pronounce it equal to its jute rival. Cotton-stalk bagging is less inflammable, and is only a shade darker than jute. Cotton circles here are jubilant."—*Southern Planter*.

SUGAR IN INDIA.

Papers respecting the sugar production of India have been received from the Secretary of State for India, from which the following particulars have been extracted:—

On the 8th May, 1889, Messrs. J. Travers and Sons, Limited, wrote to the Under Secretary of State for India—

"The average production of India is given as a ton of sugar per acre, and the produce (with the exception of the three modern mills in Madras) is of the most wretched character.

"In the West Indies (which are also backward) sugar growers obtain two tons of sugar per acre, or double the Indian average, and, with modern machinery, properly crystallised sugar can be made direct from the cane juice at a cost on the spot (that is, without carriage) of 8s. to 10s. per cwt.

"It is no doubt the competition of such direct cane sugar from Mauritius which is leading to the closing of refineries in Bengal, if, as we imagine,

those refineries work, not from the sugarcane, but from coarse native sugar.

"In all the statistics sent us, Mauritius and similar sugars are described as refined, but this is altogether misleading. There are no refineries in Mauritius, whose sugar is remelted, and the produce of the island is simply raw sugar properly made by modern processes.

"It is such sugar that India ought to make, and the Empire, with sufficiently improved cultivation and machinery, might readily supply the world with sugar. Refining is a secondary process, likely to altogether die out, by slow degrees, as cane and beet manufacture becomes more perfect. The disappearance of refining in Bengal, though hard upon individuals, is really a sign that there is progress elsewhere, and progress which no country is better adapted than Bengal to share in.

"That modern sugar can be well made in India is shown by Messrs. Minchin at Aska, Madras, and it is simply absurd that India should have first to export the labour to Mauritius, and then to re-import sugar from that distant island, which could be as well made, and certainly more cheaply, at home. India is generally regarded as the home of the sugarcane, and with its teeming population, its climate, and (in some districts) its plentiful water and coal supply, it should be a large exporter of fine sugar instead of an importer.

"The manufacture of modern (or, as it is called vacuum pan) sugar, to be profitable, must be on a large scale, because it involves costly machinery and chemical and mechanical supervision impossible for ryots, who probably do not extract one-third of the sugar that might be extracted from their crops, and make that third in a shape that looks more like manure than sugar, and which appears to fetch in many parts of India as little as 6s. per cwt. on the spot, whereas Mauritius sugar in India must net double that to pay the grower.

"Vacuum pan sugar making is, probably, only possible on a large scale in India through the central factory system, where the raw canes are bought by the mill from the growers. A system similar to this already prevails in indigo and silk mills in Bengal.

"We do not know whether the Government of India would be able to start a few model factories in suitable districts, or whether they must confine their attempts to develop sugar manufacture to the collection of information and figures like those in the returns forwarded to us. In any case, the efforts of the Government in this direction for some years past cannot fall to be of great value."

This letter was sent by the Secretary of State to the Government of India, and in reply to the points there raised, a series of letters were obtained from authorities of India. The Director of the Department of Land Records and Agriculture, North-West Provinces and Oudh, wrote:—

"The suggestions made by Messrs. Travers and Sons is that the Government of India might start a few model factories for the preparation of sugar by modern processes in suitable districts. This appears to be the only point of practical import new in the memorandum. In my opinion the Government would be ill-advised were it to act on the suggestion. I base my opinion on the general ground that private enterprise in India is now sufficiently altered and well organised to undertake the business of sugar-refining on a large scale, and with ample capital if there were a reasonable prospect of success. That sugar-refining companies working on scientific principles, such as the Rosa Company and the Aska Factory, show no signs of multiplying in India is to my mind a clear proof that, under existing commercial conditions, the prospects of successful trade are small. Nor is the explanation why prospects are not encouraging far to seek. European sugar refineries in India have two markets, and two only, open to them. They can manufacture for export to Europe, in which case they have to contend with the bounty-aided sugars of the Continent, and are no more able than the Mauritius factors to make a reasonable profit on their capital in such a market. Or they can manufacture for

local consumption in India, endeavouring to supplant sugars refined by native or crude European processes, and sugars imported from the Mauritius. Here they are met with the great difficulty that the mass of the native population regards with dogged suspicion all machine-made sugar, holding it to be impure and contaminated with bones and blood. The market is thus a very small one, and the prices ruling in it are by no means improved by the quantities of similar sugar thrown in despair upon it by Mauritius planters. Assuming that the cost of producing a given amount of crystallised sugar by modern processes is about the same in India and in the Mauritius (and from such information as I have at hand, I do not think a sugar refinery in India could manufacture cheaper than the Mauritius planter), what are probabilities of commercial success? They are bonned, it seems to me, by the actual success attained by the Mauritius planters, and as we are constantly told that sugar in Mauritius does not pay, scientific sugar-refining in India is not a hopeful industry. The Rosa Factory in these provinces depends more on its rum than on its sugar, and I believe this is the case with the few other similar concerns existing in other provinces.

"The memorandum refers in contemptuous terms to the quality of the common sugars consumed by the Indian public. But they have an almost unlimited and active market, which is at present closed to machine-made sugar; and even if superstitious prejudices could be overcome, there would still remain the question of national taste. The compost known as *gurr* has a peculiar flavour which is absent from machine-made sugars, and the tastes of a most conservative people will require to be changed before the local markets of India really open to the European sugar manufacturer.

"I admit all that the memorandum says as to the smallness of the yield of sugar per acre in India, as to the inferiority of the processes employed to extract the juice and make it into sugar, and as to the low quality of the so-called 'refined sugars' of India. But it is conceivable that these rude processes and this small output may yield a profit, while scientific processes and high cultivation result in a loss. Not only does the Mauritius system require a large initial capital expenditure, and a large annual outlay, but it also requires a highly paid supervising and controlling agency. I do not defend the imperfections of the Indian system, but I think it is economically explicable.

"There would be some difficulty in introducing the Mauritius system bodily into India, since a prominent feature of that system is that planting and manufacturing are concentrated in the same hands. But as the memorandum points out, a sugar refinery might easily work in an Indian sugar-growing district on the line familiar to indigo planters. It would buy cane at the proper season from cultivators of the neighbourhood, and would restrict its interest in the actual production of the crop advances to growers. A large sugar refinery, I may point out, would have to face two problems which are not easy to solve. The first is the question of carriage. Cane soon dries when cut, and cannot be carried long distances. A sugar refinery has thus to depend for its raw material on a small area devoted almost exclusively to the production of sugar, and this is opposed to the habits and traditions of the Indian agriculturist. The second difficulty is that the machinery of the factory would stand idle for a great part of the year, and occupation would not be forthcoming for the hands, unless a subsidiary business, such as the manufacture of rum, is added to that of sugar refining. The market for rum in India is not large, and is probably sufficiently supplied by existing concerns."

Mr. M. Finucane, Director, Department of Land Records and Agriculture, Bengal, wrote:—

"As regards the question of improvements in manufacture suggested by Messrs. Travers and Sons, I would remark that it seems not unreasonable to suppose that such improvement is possible and it is not improbable that the establishment of model

factories in suitable districts, whether by Government or by private individuals, encouraged or subsidised by Government, would yield beneficial results. Messrs. Mylne and Thomson, in their letter dated 28th February 1880, to the address of the Collector of Shahabad, reported that they had for years been trying whether cane could be profitably purchased and worked off at a central factory, and the conclusion to which they came was, that the price demanded for cane by the growers, which price the growers realised by making it into *goor*, was so high, that the experiment was not deemed to be profitable and was discontinued. Messrs. Mylne and Thomson added that the Rosa Sugar Works at Shahjehanpore had not found it advisable to make arrangements for crushing cane and making refined sugar from the juice direct, and the inference would seem to be that central factories, such as are suggested by Messrs. Travers and Sons, will not pay. The reason given for this is, that the factory could not work at a profit, if it paid as high prices for the cane as the cultivators realise by making it into *goor*. But this is only stating the fact in another shape, and is no explanation of the problem—why is it that with cheap labour, cheap raw material, refined sugar cannot be manufactured in India at a lower price than that for which it can be imported from the Mauritius or England? A similar question may be asked as regards other products, for example iron—why is it that with cheap labor and cheap iron ore at Ranigunge, it is found profitable to import manufactured iron articles from England? I am not at present in a position to furnish an answer."

The letter from the Government of India to the Secretary of State, covering the correspondence is dated "Calcutta, 24th December, 1889," and is as follows:—

"The improvement of sugar production and manufacture in this country has been the subject of attention both of the authorities and of capitalists since the beginning of the century, and various attempts have been made to establish factories, none of which appear to have been attended with any permanent success unless supplemented by the sale of rum and liquors. Sugar refining alone has not proved sufficiently profitable to maintain a factory. If this had been the case, there appears to be no reason why the industry should not have been largely taken up by private capitalists.

"Some of the main difficulties against which the industry has to contend are believed to be these:—

"(a) The cultivation of sugarcane is limited by the supply not only of water for irrigation, but also of manure.

"(b) As cultivation in India is confined to small farms or holdings, each cultivator who is able to grow the crop at all can only find manure enough for a small area, generally less than half an acre, of sugarcane. The plots of sugarcane are therefore greatly scattered, even in a canal-irrigated tract.

"(c) A central factory has accordingly to bring in its supplies of cane in small quantities over varying distances, in many cases the distance being great.

"(d) The carriage of canes over a long distance, even in a climate like that of the Mauritius, is detrimental to the juice for purposes of sugar making. It is much more so in India, where the canes ripen at the season when the atmosphere is driest and suffer, therefore, the maximum of injury.

"(e) The Mauritius system of growing large canes at intervals is not adopted to the greater part of India where, in order to prevent the ingress of dry air into the fields, small canes have to be grown in close contact.

"(f) The amount of cane which can be grown, limited as it is by the supply of water and manure, barely suffices for the wants of the Indian population. It seems to be at present as profitable to produce coarse sugar for their use, as highly refined sugar for export. There is, therefore, no sufficient inducement to capital to embark on the more difficult and expensive system.

"A further obstacle to sugar refining in India

exists in the high differential rate which the conditions of our excise system require to be placed upon spirits made on the European method, as compared with that levied on spirits manufactured by the indigenous process. The sugar refiner in India is thus placed at a disadvantage in respect to the utilisation of his molasses in the form of spirits.

"In view of the circumstances above noted, we are unable to advocate any attempt being made at the cost of the State to establish model factories. We are inclined to attach much confidence to the views and conclusions formed by Messrs. Thomson and Mylne, who have paid, for many years, practical attention to the subject of sugar cultivation and manufacture by ryots, and were the first to introduce the portable sugar-mills which have now spread over India. They advocate the gradual improvement of the ryots' method of manufacture rather than the introduction of more expensive and centralising systems. The Provincial Departments of Agriculture have of recent years, directed attention to this question, and may usefully be desired to continue to do so.

"We are also willing to advocate the establishment of agricultural experiments in those comparatively limited tracts of the country (such as Eastern Bengal, where there is a moist climate and a more or less abundant supply of manure) in which the Mauritius methods of cultivation have *prima facie* prospects of success, and we are prepared to advise our Local Governments and Administrations to give every reasonable support to sugar factories and refineries which may be established by private enterprise."

Messrs. Travers's reply to the correspondence is dated 21st February, 1890:—

"We observe that while all the officials who have reported fully confirm our information as to the great, and indeed excessive, waste in Indian sugar manufacture, yet that they are able in some degree to explain the causes of the existing state of things, while the opinion is general that it would not be wise for the Government to establish experimental central sugar factories.

"It would be presumptuous on our part to offer any comments on a question so fully taken up by the local authorities on the initiative of the Secretary of State.

"It only remains for us, in concluding the correspondence, to acknowledge the very great courtesy with which our necessarily imperfectly informed remarks have been received, and the promptitude with which action has been taken owing to the recognition by the India-office and the local authorities of the great importance of sugar manufacture to India, and the possibility of a great development in it.—We are, &c.,

"Pro. J. Travers and Son, Limited.

"(Signed) J. W. Rogers.

"P.S.—We may mention that 'German granulated,' a small white dry crystal sugar made direct from the beetroot, is now being shipped from Hamburg to India; so that the ryots will not have Mauritius only to compete with at home. We believe this sugar costs about 16s. per cwt. laid down in Bombay, and that the bounty on its export does not exceed 6d. to 9d. per cwt."—*Journal of the Society of Arts.*

LIME AS A PREVENTIVE OF MILDEW AMONGST CUCUMBERS AND MELONS AND FOR POTATO DISEASE.

In cases of mildew among cucumbers and melons and disease among potatoes, lime is an invaluable article. If applied wherever the disease has manifested itself, it will prove an effectual remedy, but if any part of the plants affected is not touched with the lime, the disease will not be effectually stopped. The best way to apply it to cucumber vines affected by mildew is to sprinkle the powdered lime under as well as over the leaves by means of a small sieve. This should be done early in the morning when the leaves are damp from the night's dew. Plants that have been nearly dried up by the dis-

ease, will frequently take on a new growth in a few weeks with a steady application of lime.

Applied in the same way to potato stalks that have been dried and eaten up by disease, the lime has similar good results. When the disease has eaten so far down into the heart of the stems that the roots of the potatoes are affected, the application of powdered lime will not have much effect. Unless the disease has, however, made such rapid headway, it will pay to give the whole field a treatment with lime. The greatest care should be taken to sprinkle them carefully, sifting the lime on all parts of the leaves and stems that are affected in the slightest degree. Very many potato fields could be saved from partial or complete destruction in this way.—*Southern Planter*.

NOTES ON ESSENTIAL OILS.*

Sandal-wood Oil.—At the Government auctions of sandal-wood held at Mysore in November and December last the following quantities were brought forward:—

	Tons.
From the Shimoga district.....	770
From the Kador district.....	200
From the Hassan district.....	300
From the Mysore (Seringapatam and Hunsur) district.....	1,000
From the Banwaloro district.....	150

while the auctions in previous years show the following quantities:

Year	1883	1884	1885	1886	1887	1888
Tons	2,600	2,775	2,650	2,025	2,450	2,500

The assortment usually consists of 15 per cent. of root, 20 per cent. of best-quality logs and the remainder of second quality logs and chips. Unexpectedly high prices were paid for all qualities, for whereas the values had been, superior 46s 6d., roots 44s. 9d., ordinary 40s., c.i.f., the whole of the quantity brought forward sold rapidly at 54s. 6d. for superior, 52s. 9d. for roots, and 46s. 6d. for ordinary, an increase of 20 per cent. It is believed that for a long time to come the article will be maintained at high prices, as the government of Mysore has again taken energetic steps to obtain the full benefit of this monopoly. In future only so much good is to be cut down as required for the consumption, and it seems to be the object of the Government gradually to increase the price of the wood, and then to keep it at a definite point. Of the whole of the wood, which is sold, about two-thirds is used in India, partly for carving, and partly as an incense in religious ceremonies, and only about one-third is consumed in Europe. If, in spite of this advance in the price of the raw material, the cheap oil from East Indian wood is frequently offered, cause may be found in the use of Macassar sandal-wood oil, which very nearly approaches the Indian oil in quality, although for perfumery purposes the Indian oil deserves decidedly the preference.—*Oil, Paint and Drug Reporter*.

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F.L.S., F.G.S., &c.,
EDITOR OF "SCIENCE Gossip."

The artificial manufacture of rubies is still going on, and a trade demand for them has arisen for use as pivots in watches. They are stated to be not inferior to the natural stones in hardness. The two French chemists who have been long experimenting on the subject have been able to produce much larger stones than formerly by a modification and improvement of their original method. As much as six pounds of rubies can be produced at each operation. These experiments show that the colours both of natural rubies and sapphires are due to chromium in different states of oxidation.

Indigo can now be artificially produced by two different methods, worked out independently by two or three different experimenters, all German chemists.

One is produced with phenylglycocino and the other from anilidocetic acid.

Dr. Alfred Carpenter, of Croydon, the well-known sanitarian authority, in an address recently delivered before the Association of Sanitary Inspectors at Liverpool, estimates the loss to England from the non-utilisation of sewage, during the last 800 years, at 16,000 millions sterling. He declared that if our present wasted sewage could be put upon the land, meat and milk would be produced over that yielded now, and five times the amount of labour would be employed thereon. He contended there should be from 5,000 to 6,000 tons of sewage placed on every 35 acres of land, from which 40 to 50 tons of produce per acre would be obtained. Moreover, he argued that, if properly treated the land would be freed from excess of nitrogenous matter, and there would be a complete purification of the water supply. He did not say, however, how the latter could be effected. I imagine you would find it difficult in Australia to put 50 tons of sewage on every 35 acres of cultivated land. Even in our densely-populated country we cannot do so. Consequently our British bill for artificial manures is a little over five millions a year.

The official report issued by the U. S. A. Department of Agriculture at Washington shows a falling off in the wheat cultivation of America during the last decade. In the year 1880 the total production was 498,549,868 bushels; in 1890 it was reduced to 399,262,000 bushels, nearly one-fifth less. Maize yielded in 1880 1,717,494,543 bushels; in 1890 only 1,489,970,000 bushels, although this is a characteristic American crop. On the other hand, the yield of oats had gone up, perhaps owing to the large increase in the number of horses employed. In 1880 417,858,380 bushels of oats were produced; in 1890 the yield had increased to 523,621,000 bushels.

From some important experiments by Professor Henry, the principal of the Wisconsin Agricultural Station, as to the relative fattening properties of barley meal and maize meal, it appears that it required 36lb. more barley meal than maize meal to produce 1,000lb. of meat. The experiments were on ten hogs, 14 months old, extending over a period of eight weeks. Both feeds were soaked with water, and it was found it required about three pounds weight of water properly to soak one pound of barley meal, and only two pounds of water to soak the same quantity of maize meal. The hogs fed on barley meal consumed 30lb. of water daily with their food, while the hogs on maize meal only required 22lb. Even with this large amount of water in the feed, the barley-fed hogs drank two pounds a day extra, from a separate trough, whilst the maize meal fed hogs only required three-quarters of a pound extra daily.—*Australasian*.

THE PROJECTED JAVA QUININE-FACTORY.

We mentioned recently that the Java planters intended to send a chemist well acquainted with the cinchona industry to British India to report upon the quinine-works existing there, with a view to the establishment of a factory in Java. The mission, however, is not likely to take place, as the necessary funds have not been forthcoming. A correspondent of the *Indische Mercur* states that two years ago he inspected the works at Nadjeatam and Mungpo, in India, but found the process used there quite unsuitable for the proper manufacture of quinine. Although since then Messrs. Lawson & Hooper have improved the process in several particulars. He happened to meet in India one of the largest European quinine manufacturers, who had also visited the two factories, and spoke of the process followed there with contempt, saying that, if the freight were not too heavy, he should be glad to buy the already extracted barks from those factories, because the alkaloids are very imperfectly taken out.—*Chemist and Druggist*. [We doubt the bona fides of this critic, considering the cheapness of the bark in its original state.—Ed. T. A.]

* From Messrs. Schimmel & Co.'s report.

Correspondence.

To the Editor.

THE PUSHING OF CEYLON TEA.

Nuwara Eliya, April 24th.

SIR,—Why do we neglect the opportunity placed at our doors of advertising our tea at a nominal cost, and with more far-reaching results than perhaps any other scheme; and why do we permit rubbish not fit to be called tea to be sold as such to the passengers in our harbour and the visitors to our shores, thus seriously injuring the name of Ceylon? Perhaps we neglect it because it is so easy of attainment in the same way that few of us residents have climbed Adam's Peak, although we have lived close to it for years, while thousands come from all parts of the world to ascend it. But, whatever the reasons may be, should not the Planters' Association (more especially in view of recent revelations) take the matter in hand at once?

I would suggest the following as a very simple scheme, which would be an immense advertisement for Ceylon and lead to a lot of future orders from abroad, reaching every country and nation on the globe, and at the same time choking off all the inferior rubbish at present sold in the harbour, which is ruining the name of Ceylon tea. Perhaps you, Mr. Editor, could add a foot-note stating the number of passengers last year and their destination, which would better enable us to estimate the possible results.

(1st.) I would have the Planters' Association arrange with all steamer agents to give them (the Planters' Association) the exclusive right to sell tea on board ship in Colombo harbour. This is necessary, and the Planters' Association should in return promise to sell the tea as an advertisement at cost price (including packing and selling charges).

(2nd.) At every port nearest to Ceylon on the principal routes to it a stock of pamphlets should be held by an agent. These pamphlets should contain a concise history of Ceylon, some interesting information about Ceylon tea, and an advertisement of the Planters' Association announcing that tea at cost price would be sent on board that ship as an advertisement when she reached Colombo harbour. The agents of all steamers visiting Singapore, King George's Sound, Calcutta, Aden, etc., would be glad to have these pamphlets distributed on board ship to their passengers, and the passengers would be equally glad to read them, as a description of the country they were coming to, with the result of a sale of tea in a great many cases.

(3rd.) To make the scheme a complete success, the Tea Kiosk should be taken over and worked together with it by the Planters' Association. Some Rs15,000 have already been spent on the Kiosk, and there is very little to be seen for the money; but I believe good returns could be got from it in connection with this scheme. I would propose to do away with the high-sounding title of "The Kiosk," which half the passengers don't understand, and in large letters on a signboard put something like "Ceylon Planters' Tea Room;" "Tea sold by cup and packet at cost price," etc., and show its position on a map of Colombo in the pamphlet.

(4th.) The tea sold should be a blend—or blends—and made by a committee of local experts, and should be *uniform in quality always*; those gentlemen would, I have no doubt, give their services free.

(5th.) A considerable stock should be held to execute further orders from abroad that would be sure to follow from private individuals and tradesmen who found the tea suitable to their requirements. This feature of selling further supplies is objectionable, inasmuch as it is introducing an element of trading into what is really an advertisement, but better do a little trading than leave a loophole for the failure of the scheme.

In conclusion two instances that have recently come under my notice go to prove the desirability of carrying out some scheme such as I suggest.

A.—I saw a cart load of 10 lb. boxes neatly got up by a European firm (who did not know their destination I may say) in charge of the owner—a native—on the way to the wharf for sale on board-ship. I got one and opened it, and it contained the most ghastly rubbish I ever saw, not worth 8 cents a lb. The price was Rs8 or Rs10 per box, I forget which! Is anything calculated to damn Ceylon tea more than this?!

B.—A friend of mine who sells part of his tea through one of the Fort shops, Cargill's I think, has had orders for the last three years from an Australian grocer, who got his first lb. in the Colombo shops, increasing yearly till this year (1892) he has an order for 30,000 lb. of pekoe at highly profitable rates.

One can easily imagine the disgust of the passengers when they are swindled in CEYLON over our staple product; and I consider it the duty of the Chairman of the Planters' Association to be up and doing in this matter before further damage is done to the planters when the remedy is of such easy application.—Yours, &c., L. D.

[We are unable at the moment to say what was the number of European passengers in 1891. Our correspondent fixes no limit to the quantity of tea which is to be sold at cost price, and does not take into account the interference with private enterprise.—Ed. T. A.]

ON THE BURNING OF CATTLE MANURE AS FUEL.

Analytical Laboratory, 79, Mark Lane,

London E. C., April, 8th, 1892.

GENTLEMEN,—I have much pleasure in sending you a copy of Dr. Voelcker's long expected lecture on the Agricultural Needs of India which was given last night at the Society of Arts and a which the late Sir James Caird was to have taken the chair. As you will notice and indeed as might reasonably be expected Dr. Voelcker was not able to suggest any new improvements but only an extension of those already largely in force. A judicious construction of canals, and of well sinking under careful supervision and consideration of the local agents of the Government, also the increased establishment of forest reserves with a view of improving the climate and also of furnishing wood as fuel. Speaking of the subject of manure being used as fuel in certain districts Dr. Voelcker strongly condemned the practice, though he was unable to point out how under existing circumstances and in the absence of wood suitable for fuel, the present custom could be materially altered or imposed. It is in fact a matter of necessity and not of choice, and until new forest reserves are established the poor natives are likely to continue to burn the cow-dung cakes or bratties for many years to come.

Indeed as pointed out by myself in a note published in the *Journal of the Society of Arts* for March 21st, 1890, this practice of burning bratties is after all not so wasteful as might at first sight be supposed:

According to my new analyses of sun-dried cow-dung cakes every ton of these bratties contained in round numbers the following quantities of the important plant food constituents.

Lime	43 lb.
Nitrogen	33 "
Potash	14 "
Phosphoric acid	12 "
			102 "

When such a manure is burned as fuel the nitrogen which originally in the manure existed as organic matter becomes converted into gaseous products which are either directly absorbed by the growing plants or crops in the neighborhood or are carried down by the rain into the soil and retained for subsequent use as plant food.

The loss, therefore, of nitrogen by the use of cattle manure for fuel purposes is by no means as complete as is generally supposed to be the case.

While the whole of the mineral salts including the valuable lime potash and phosphoric acid are retained in the ashes which under proper sanitary arrangements ought to be carted out on to the land together with the usual house refuse and vegetable rubbish always associated with domestic dwellings. It should be remembered that about 80 per cent of the atmosphere consists of free nitrogen, and that according to the most recent scientific research leguminous plants such as clover, peas, beans, &c., have the property of absorbing nitrogen from the air and so yield large crops of valuable food, as well as by virtue of increased root development increasing the nitrogen in the soil, so that not only a good crop has been obtained but the soil is actually enriched and better able to produce other crops of a different character. In a smaller degree, most crops may be expected to absorb nitrogen from the air, so that in tropical climates it may be found that nitrogen is of all the important plant foods the one which can be most easily obtained by natural means, and if so its artificial supply in the form of manure may be dispensed with the least loss.

Certainly the custom so general in India of burning the stubbles after harvest and so destroying the straw left on the fields would tend to confirm the view that nitrogen in the form of organic matter is not so much required by the soil of the country as might have been supposed, bearing in mind too the well-known mechanical advantages of farmyard manure; also its moisture holding properties which in a hot country would strike most observers as of special value.

Again the fact that some 40 to 50 thousand tons of bones and bonemeal are being now annually exported to Europe, still further proves that there cannot be any great demand of really first-class fertilizers in India. Indeed a country which has produced year by year crops of corn, rice and gram for centuries without suffering any appreciable loss of fertility in the soil can probably afford to go on for centuries in the same manner. At the same time there should be judicious improvements of existing customs and practices, as it would be most unreasonable to maintain that no improvements were necessary in order to provide for the vast and rapidly increasing population.

In the past periodical famines prevented any undue increase of population, but with the extension of railways and improved transit, the starving people can be readily reached with supplies of rice, so that aided by thoughtful and energetic administration famines will not prove the terrible scourge they did in former times when thousands died in certain parts of that vast continent, while in other parts there was an abundant plenty.

In the discussion which followed the reading of the paper Professor Wallace supported the present practice of burning cattle manure chiefly on the ground of the necessity of the case, pointing out that until wood or coal was provided by the authorities the poor natives were not in blame. For myself I am always inclined to believe that local customs are usually the result of sound and long established experience, and in the foregoing remarks I have ventured to put forth my views in support of the present custom by way of explanation rather than of any new principle or theory.

JOHN HUGHES.

[There is this qualification. The practice of burning cow manure as fuel is defensible because there is no wood. But why is there no wood? Because the people keep the all-devouring animals, goats. These beasts are amongst the most formidable enemies of forestry in India.—Ed. T. A.]

THE MADRAS AGRI-HORTICULTURAL SOCIETY:

—The Madras Mail of 14th May 1892.—

The Committee of the Agri-Horticultural Society of Madras recently brought to the notice of the Madras Government that for a period of 35 years, or from 1854 to 1889, seeds to the value of Rs.4,000 annually were, by order of Government, purchased from the Society by regiments serving in this Presidency, but that since 1889, in accordance with an order of Government all indents have been made on the Government Botanical Gardens at Ootacamund. The result of this has been a serious loss to the Society, which was established in 1855 for the promotion of agriculture and the encouragement of improvements in agriculture generally. The Society claims to be the only body in the Presidency which the Government can consult and seek assistance from in introducing new plants or improving those indigenous to the country. Such advice was, it is urged, often asked and always cordially given. The Society has also for many years supplied seeds to and prizes for the products of soldiers' gardens, and aided the Government in the introduction of Mauritius sugarcane, which now grows in all the sugar-growing Districts in this Presidency; and it established a nursery for raising and distributing species of timber trees, foreign or peculiar to other parts of India. During the American War the Society tested every procurable species of cotton, and furnished much valuable information to Government as to the commercial value of the fibre of each and its suitability for the climate of Southern India. The Society has also been of great service in the teaching of botany in the Government Medical College, the Presidency College and the Agricultural College at Saidapet. Specimens of plants are supplied gratuitously for the Lecture Rooms of the Professors, and the pupils regularly visit the Society's Gardens to receive practical lectures on the plants growing there. The Society was the first body in India to institute a scientific inquiry into the natural history of coffee borer and to seek to obtain some remedy for its terrible ravages which have caused such loss to the planter. Further Dr. Bidie, the then Honorary Secretary of the Society, was selected by the Madras Government to carry out the enquiry into the ravages committed by the insect and suggest a remedy therefor. His report was published by the Madras Government and Dr. Bidie was thanked for the manner in which he had conducted the enquiry. Considering, therefore, the great and valuable services rendered by the Society in the Presidency generally, and the fact that without the Government subsidy, according to the Committee, the Society cannot exist, the Committee requested the Madras Government to order that the privilege of providing seeds for soldiers' gardens should be again restored to the Society. We hear now that Government has declined to sanction any alteration in the existing procedure under which seeds for soldiers' gardens are now supplied, as the present arrangement was sanctioned by the Government of India after mature consideration, and in view to assimilate the practice with that obtaining in Bengal and Bombay.

FROM THE METROPOLIS.

22nd April 1892.

TRADE AND INDUSTRIES OF EAST AFRICA.

Two Consular Reports recently issued contain matter of considerable interest to Ceylon readers—planters and merchants. ZANZIBAR, under new auspices and as a free port, probably may become the great entrepôt of trade for East Africa and this is the end arrived at by Mr. Portal, who reports to Lord Salisbury for 1891, as follows:—

The total declared value of imports from all parts of the world during the whole of last year amounts to 153,79,691 rs., or 1,205,691 10s, whereas the estimate made in November, based on the return of the previous ten months, gave 1,300,000 as the probable figures for the whole year. No stronger argument could have been found in support of the contention that if Zanzibar is to maintain its pre-eminence it should, without loss of time, be declared a free port. That principle has now been accepted by Her Majesty's Government, and the formal declaration will be made on February 1.

To turn to the exports from Zanzibar. A complete tabular statement is now enclosed showing the quantities and value of each class of goods exported, and the ports to which they were consigned. The gross value of the exports during the year amounts to 1,384,233, or about 30,000 above the average shown by the ten months reviewed on November 17. The relative values of the different classes of goods exported is about the same as it was in November. Nothing need, therefore, be added to the remarks made under this head at that time.

Finally, although these returns and statistics still leave much to be desired as regards both completeness and accuracy, yet it should be borne in mind that this is the first yearly commercial statement that has ever been compiled in Zanzibar. The initiatory difficulties in the way of establishing an orderly system at the custom-house were great: an efficient staff had first to be formed and then trained to their work; exporters and consignees had to be requested and even pressed to make a declaration of the nature and value of their goods—a request which was for many months strongly opposed by several firms; and the dhow trade, hitherto quite unlicensed, unwatched, and unrestricted, had to be brought under at least a partial supervision, though this, I may add, is as yet very far from sufficient.

The subordinate official class and the trading public in this country are undergoing a process of education which was begun only a few months ago; until that education is completed, statistics and returns may be an approximate estimate, but they cannot be a thoroughly correct index of the trade and prosperity of the Sultan's dominions.

The peculiarity of the statistical tables given is that very much the same products (and quantities) are entered as Imports (from Africa) and Exports (from Zanzibar to Europe). It is only necessary to notice some of the chief exports. Of Cloves, the total weight in 1891 is given at 13,233,400 lb. in 94,560 packages of 140 lb. each. London got 16,294 packages, New York 22,041, Hamburg 10,669, Marseilles 8,910 and so on. The total value is put down at \$1,134,723. The next biggest export is of "Cyra" to a value of \$302,065 for 10,572,275 lb. over three fourths of which went to Marseilles, 1 10th to Bombay and 50 packages or 8,750 b. to Colombo. Next was "Rubber" exported to a value of \$221,768, total weight 491,680 lb., nearly all sent to London. Then we have "Hides," value \$185,963; Gum Copal, value \$156,600; Tortoise shells \$89,600; Chillies (to London, New York and the European Continent) \$58,454; Gum Arabic \$12,180; Cowries \$9,708; Coconuts \$2,300; Tobacco \$2,340; Rhinoceros Horns \$19,104; Shark-fins \$5,904; Wax \$8,208; Orchella \$12,730; besides from Betel-nuts, Opium, Colombo-wood, Gum-myrrh and Tiger-skins; be-

side, above all, Ivory Tusks exported last year to a nominal value of \$3,584,900.

On the trade of Mozambique, the figures are not nearly so detailed. All we are told is that the total exports of seven districts equalled £283,222, against imports £709,190. But there are interesting remarks in Mr. Oburchill's Report, more especially in reference to the Pearl Oyster reefs south of the Zambesi road. I quote as follows:—

The number of deaths registered during the year has been 743, or about 200 to the 1,000 of the whole population. The death are entered in the lists as having resulted from the diseases predominating in most tropical and malarial districts, though the percentage of 200 to the 1,000 is excessive for even unhealthy regions.

The fever prevalent amongst the Europeans here is rarely in itself pernicious, although, with prolonged attacks of fever, the system is so prostrated that some other disease usually sets in and causes death. There are many reasons given for the great unhealthiness of the climate. The principal ones are: bad and insufficient food; houses inadequate to resist the sudden atmospheric changes; the total absence of any social enjoyment or entertainment; and the impossibility, on account of the sandy nature of the soil, of taking any legitimate exercise. One depends mainly upon tinned provisions for food, and tinned food is not invigorating.

The majority of houses are built of corrugated iron and wood, and although such houses can be built cheaply and quickly they are too hot in summer and too cold in winter, and tend to increase unnaturally the climatic pressures one has to bear.

There have been 600 emigrants sent from Portugal to Lourenço Marques this year. A few of these emigrants obtain employment such as has been formerly given to the natives, a large number die, and the remainder are without work or the desire to obtain any; and are consequently a source of expense to the authorities.

The rates of wages in this district are as follows:—

Description	Amount.	
	£ s. d.	£ s. d.
Native and emigrant labourers	Per day 0 1 6	to 0 4 0
Native masons	do 0 6 0	0 12 0
Indian do	do 0 12 0	1 8 0
Chinese Carpenters	do 0 15 0	1 10 0
European do	do 1 0 0	1 10 0
Indian painters and colourmen	do 0 10 0	1 5 0
Native servants	Per month 1 0 0	5 0 0
do cooks	do 2 10 0	10 0 0

There are no industries in this district. The natives in the interior plant small patches of ground around their kraals and produce small quantities of cereals for their own consumption. The natives who live near the towns on the coast, although having ground that would produce heavy crops, find it more profitable to work for Europeans, and buy from them such food as they require. With the high rates of wages obtained they are both able to live better in this way than they could by cultivating the ground, and to have a surplus with which to drink or to buy such luxuries as they may desire.

Among the Europeans such energy as has been expended has been rather in the direction of expeditions to the interior, and in discussing political questions of boundaries, &c., than in paying attention to the nature of the soil, its cultivation, or its possibilities.

There exists on the east coast, south of the Zambesi River, reefs of pearl oysters, of which the most important is situated to the south of Chilokane, in the Bazaruto Archipelago. The greater portion of the reef is within enclosed waters, and, as it has never been regularly worked, the pearls which could be found there must be considerable dimensions. The natives in the locality of the pearl reefs occasionally find black pearls of great beauty, but their value is

absolutely destroyed in consequence of the method employed in extracting them from the shell. This method consists in placing the oyster in the fire.

A syndicate is being formed in Lisbon at the present time for the development of those fisheries.

In the month of August of this year the first fully granted Mining concession for mining of any description in this district was given to a Portuguese syndicate for the development of diamond mines situated about 37 miles from this city, near the railroad.

Other mining concessions for the development of coal, gold and precious stones have been applied for, but have not yet been granted.

Valuable coal deposits are said to exist in this district in large quantities. As, however, according to law a mining shaft cannot be sunk more than 6 feet before a concession is fully granted to work the mine, the samples of coal produced have been taken from the surface, and the real quality of the coal in the mines themselves has not yet been ascertained.

The same public works which were in hand last year are in hand this year. Those that were in contemplation have not yet been begun. All public works came to a standstill over six months ago, when such funds as were available were used for expeditious purposes.

The Netherlands Railway Company, which is connecting this port with the trade centres of the Transvaal, is completing its line to within a few miles of Barberton.

An survey is being made with the idea of constructing a railway from Komati Poort, at the frontier of this district, to the Salati River goldfields, and thence to Mashonaland. The proposed route would be three times the distance to Mashonaland that the proposed Beira route would be, but it is held that the advantages obtained in opening up the Salati goldfields on the way would more than equal the disadvantages of the more lengthened route. A large tract of valuable farming and grazing country would also be reached by a Salati River railway and homes could be established for thousands in a country practically, healthy and capable of producing payable crops of all South African produce. The proposed route, however, also runs through a country full of rivers, and is so hilly in places as to be almost impassable. The cost of building a railway in such a country leads one to imagine that it will not be attempted.

A company is about to be formed in this city for running trams for passengers and freight from the principal thoroughfares in town to the residential quarters on the hills surrounding the bay. The trams are to be propelled by steam. The company is to have the monopoly of all public delivering, and the financial success of the enterprise is in this way partly secured.

During this year a chamber of commerce has been formed by the merchants, with the idea of obtaining certain privileges in trade which do not at present exist. The chamber, however, seems to be a political as well as a commercial association, and it is a question whether any material advantages will be obtained by the department.

It has been decided by the Portuguese Government to open up the country south of the Zambesi River by means of chartered companies. One of these companies, the Portuguese East Africa Company, has a block of territory bounded on the north by the river. On the south the influence will extend to the Limpopo River, and on the east to the ocean, the islands near the shore coming within its jurisdiction. The company is compelled to construct a railway, connecting either the Transvaal Railway or the Matabelo country with the Limpopo River at the point where it ceases to be navigable (a distance of about 70 miles from its mouth); or with the port of Inhambane; or with any railway system north of the Sahl River, according to a future agreement to be made between the Government and the company. It is also authorised to grant sub-concessions, with the approval of the Government, for pearl, coral, and amber fishing.

Other companies are to be formed for the development of the remaining territory south of the Zambesi, and it is hoped in this way to open up the country

both rapidly and thoroughly by introducing industries which, without doubt, could be followed to advantage in most of the luxuriant valleys that extend along the coast a few miles inland.

CEYLON TEA IN AMERICA.

Further information respecting Mr. ELWOOD MAY'S mission to England on the present occasion does not prove very encouraging in respect of the prospects of the Ceylon-American Tea Company. No one can say in view of all that Mr. May has done in securing attention to Ceylon teas on the part of public men and the press—and specially by large advertising contracts—that he has not worked well, and entirely without fee or reward, for Ceylon tea. He has done so, as he says, because he has believed and still believes in the product as a thoroughly good article which his countrymen do well to consume in place of the inferior, and in many cases adulterated, trashy China and Japan teas. But to change the taste of a people like the Americans so completely won over for many years to a liking for the green "faced" teas is not an easy matter, as Mr. May has found to his cost; and yet he is quite certain that the lines on which he has proceeded are the right ones—that he has been laying a good foundation on which to build; and that if the process can only be persevered in, the building slowly, but surely proceeded with,—success is certain in the end. But meantime, as I have already stated, the "sinews of war" seem wellnigh exhausted. The trade of the Company so far has not been self-supporting—far from it. Messrs. Watson & Farr—to whom the greatest credit is due and the special thanks of every Ceylon tea planter—are out of pocket, if report speak true, to the tune of £3,000 to £4,000 sterling, and naturally, they do not care as men of business, rather than of speculation, to advance further unless simultaneous support can be got from those more immediately interested. So with Mr. May himself, any further effort beyond the Atlantic for this Company depends on co-operation in England or Ceylon or both. Already the rumour is that the store of the Company in New York which Mr. Pinco managed, and for which a heavy rent was paid, may have to be, or has already been, closed; and Mr. May makes no secret that unless his mission is crowned with some degree of success he will see an honourable man have to throw up the advertising contracts and generally to suspend operations—in other words the Company must collapse. This would be an especially unfortunate circumstance on the eve of the Chicago Exposition; and no one seems to recognize that fact more clearly than the Commissioner, Mr. Grinlinton. He has also personally not the least pecuniary interest in the Company, of the Ceylon shareholders. One question may be whether the Company should not be in some way identified with the Ceylon Tea Court in the Exhibition. Probably as regards this point, as well as in respect of the financial requirements, the counsel of Sir Arthur Birch may be sought; and no one has manifested a greater interest in the future expansion of the consumption of Ceylon tea in America, than our former Lieut.-Governor and Colonial Secretary.

Mr. GRINLINTON, who continues very busy, is likely to make his passage by the S. S. "City of New York," the last boat in which he returned from America in 1890. Leaving Liverpool by it on 4th May he should be at Chicago by the 17th—in good time for the purpose in view. He has been seeing the American Minister, and leading American citizens in London and getting introductions to leaders in the tea import trade in New York, &c.

GERMAN v. ENGLISH MANUFACTURING CHEMISTS AND
THE OPENING IN INDIA.

My attention has been called by Mr. T. Christy to an article which has appeared in a German Pharmaceutical Journal written in a depreciatory and unfair tone towards English chemists. I send you the translation which has been supplied to me for publication, and apart from the replies and criticism which will no doubt be provoked in India as well as Ceylon. I would only mention the case of Messrs. Kemp & Co. of Bombay, who manufacture a large number of Indian preparations on the spot, and who even supply home wholesale drug houses with preparations made from the fresh products of India. Altogether Mr. Hellinz deserves a good rap over the knuckles, and it may be a question whether he has ever been in the East at all. The paper is as follows:—

A CHAT ABOUT INDIA.

By H. HELLING, LONDON.

Which appeared in the *Pharmaceutischer Zeitung* of Berlin, 4th Nov. 1892.

(Translated by a London friend for the "Ceylon Observer.")
A great deal has been written about India; and as far back as its history can be followed, new and wonderful things are heard of from time to time.

To a chemist and druggist, India is a land of especial interest, not only because products of the country have been used as medicines since the oldest times, but because the drug export even up to the present day continually offers something new and brings its influence to bear upon the whole commerce of drugs; take for example the influence exerted by East India cinchona bark. But the country is of far greater interest to the German apothecary, for in British India German influence has recently made itself conspicuous in a considerable manner. A few words therefore with regard to the conditions of commerce and the position especially of the drug commerce, may be not without interest, all the more so, as I have obtained the information (as far as the conditions of commerce are concerned) from authentic sources; and I cannot do otherwise than express my thanks to Messrs. Collingwood and Schlesinger. Mr. Collingwood only lately returned from lengthy travels in India and is well up in the drug trade, whereas Mr. Schlesinger has had an experience of many years in the drug trade, and both occupy themselves with the introduction of rare and new drugs. Starting from the fact that British India has a population of between 200 to 300 millions; this sufficiently proves of what importance such a country must be to commerce.

Until a few years back its trade lay in the hands of Englishmen and natives. Englishmen imported and exported, whereas the native has exported and found a sale for their produce in India. These conditions have gone through a mighty change of late and it is chiefly German firms that have the import trade to a great extent in their hands, competition driving English goods more and more out of the field.

The reasons for this are plain. The English are used to high profits in India since ages back, and they had hardly any occasion to deviate from this, as the wants of India were completely monopolised by England directly or indirectly, for there is no doubt that since a considerable time many Continental goods were brought to India through English houses. The ever-increasing competition together with the interest for colonial trade, has caused the German houses to take foreign commerce more and more into consideration, and what formerly seldom occurred and was hardly noticed by Englishmen has now become an unalterable fact viz. the successful appearance of German houses of commerce in India. The chief reason for this success of German industry is to be found in cheap prices, which of course outweigh everything else from a native's point of view. To a native the chief condition is cheapness, once more cheapness and again cheapness. Quality does not come into

consideration at all, they will buy small quantities of cheap things today and when used up will buy again without considering whether a dearer article might not have lasted longer. Moreover a German adapts himself more to the demand of the public and supplies to the native traders things made according to their wishes. He is not like the English who manufacture their goods as they think best, without attending to any of the wishes of the buyers. This is also especially the case with pharmaceutical and medicinal utensils such as surgical instruments, thermometers, glassware, etc., which are often supplied by Germans at a quarter of the price at which English houses offer them. A large field is open in British India for Germans, all the more so if they can settle down in the country with capital. Chemical industry in India and the manufacture of pharmaceutical preparations do not exist. Everything is imported into the country instead of being produced in the country itself.

The alcohol industry is as good as non-existing. The only thing made by everybody is artificial mineral water, and as this represents about the highest step of chemical industry there, it indicates how very backward manufacturing is in India. There is an opportunity for many a German chemist and druggist or manufacturer to work out new enterprises in the country and draw out the profits. When we consider that the native medical man and apothecary having only the crude products is obliged to take his supplies of all other preparations such as tinctures, extracts, chemicals, etc. from Europe, there remains no doubt that a golden future is beckoning many as hardly anything in the way of galenic preparations is made by the wholesale or European druggists of India themselves. It is a fact that many an Indian drug must travel first to Europe to be made into a tincture and as such be taken back to India again. This "keeping back" of industry is in strong contrast with the rising of other countries, for instance Japan which makes an Iodido of Potassium superior in purity to the English and equal to the best German brands. As regards the buyers of imported goods it is astonishing that for the greater part they consist of native agents who sell their goods in poor looking booths in the bazaars and buy and sell in wholesale or retail quantities. Many of these people are rich and have enormous businesses; most of the goods are transmitted to their clients direct.

Among the native merchants in Bombay and its neighbourhood the Parsee or emigrant followers of Zoroaster take the first place as far as mercantile efficiency is concerned and are on a par with the Europeans. It is said that three Chinese are necessary to equal one Parsee, and the Chinese are known as thorough merchants. In the bazaars everything is classified according to the different guilds; that is, we find the different branches of business together and the poison shops form a street for themselves. The business with every stranger is to a great extent simplified by the obliging manner in which he is received in the bazaars by the Parsees who with the other merchants for the most part speak English. A few more words about the Parsees with whom the Europeans have chiefly to do; they are merchants on a large scale and have a liking for home life; contrary to Europeans they acquire landed property, fine country houses of European style, and fine horses.

These are habits which hardly agree with many of their customs, as for instance the giving up of their dead to the vultures for food. In Calcutta and the surrounding districts the chief merchants are the Baboos who are said to be inferior to the Parsees. With regard to the quality of the chemicals introduced in almost all cases the requirements of the British Pharmacopœia are sufficient, although I know of cases where the Indian authorities put even higher requirements for instance that cocaine should stand McLagin's test. An Indian Pharmacopœia is in existence, but chiefly for the sake of Indian drugs used by the native doctors.

Native gentlemen continue to come in large numbers to England to study medicine where they pass the examinations and then of course prescribe quite in the English style. On looking at Dymock's "Vege-

table Materia Medica of Western India" and the "Pharmacographica Indica" now appearing, one notices that a large mass of drugs playing an important part in India medicine have not been examined, even as to their chemical and physiological action and it almost seems as if of late years in England the general interest is turned more to the examinations of synthetic chemical products quite neglecting the vegetable drugs.

This is all the more to be regretted as one can at least get authentic plants from India as the number of botanical gardens and agricultural institutes do everything to find use and demand for the raw products of the country for the benefit of it.

It would be a great pleasure to me if these lines were to excite the German chemical industry and drug commerce, on to further enterprises in India and in the English colonies in general. There is no doubt, but that in these countries a wide future lies open to Germans of this profession.

SOUTH WYNAAD NOTES.

4th May 1892.

During the last month we have had a rainfall measuring 8 inches 55 cents, which for April is somewhat unusual. This was ushered in by sharp cyclonic storms, which drifted off into an excellent imitation of the monsoon—dull grey skies and a continual dripping of soft rain. The storms were sufficiently strong to bring down no end of trees, which blocked our roads in a most inconvenient manner. The worst of it was, that in some cases the heavy rain fell upon the open blossom. This is a sensation which no one but a coffee planter can duly appreciate. To saunter round in the evening and gaze hopefully at the sheets of snowy blossom, to speak encouragingly to the bees which hum merrily round, intoxicated by the wealth of sweetness spread out for them, to eat your dinner in happy consciousness that the crop would pay for it, to lay your head down peacefully on your pillow rejoicing in the thought that "the blossom is safe, and thou," . . . crash, down comes the rain—bang, do you go the charco trees upon the finest bushes! The thunder rolls, the lightning flashes, and you lie on your back doggedly staring at the ceiling and saying to yourself, "What a glorious, happy, innocent Arcadian sort of life is that of the free and independent planter!" However, we may hope that it was only here and there that the blossom was thus caught. But here, you see, comes in one of the advantages of Liberian. The flower opens, sets, and falls within a few hours, and storms affect it not. Oh! how I longed for some of the detractors of my favourite product, to take a walk round my special plot, the morning it was "out." It was simply a magnificent sight and every passing wayfarer paused to admire and exclaim at the glorious show of lig waxen blossoms. As for the bees, they became absolutely delirious over it, such a buzzing and fusing, such a turning up of their noses at the Arabics, which looked an insignificant besides its towering brethren. I think the most rabid abuser of Liberian, after a sight of that field, however much he may have come to scoff, would have returned to plant Liberian.

I have not yet met anyone in this neighbourhood who seems especially jubilant on the subject of crop. Of course, we have different ways of expressing ourselves. Our optimists say—"Everything is splendid, though of course, we cannot expect such a magnificent crop as last year, two seasons running!" Our pessimists sigh heavily and murmur *Schabod*, and point at estates abandoned now, and move to be abandoned; moderate folks like myself steer a happy medium, or to try to, mindful of the stone-throwing proclivities of some other people. I don't think there is any immediate prospect of Wynaad turning out many millionaires in this year of grace, 1892. But possibly if the rupee keeps to its present delightfully depreciated state, we may be able to cover expenses. On several estates the crop has promised very fairly well, whilst on others,—rumour

says,—but there, let us talk of "seeing-wax a d kings," rather than dwell upon uncheerful subjects.

The long drought has been a splendid check upon leaf diseases, but we rather dread the subsequent effect of all these late rains, I hear groanings over here, but as far as I can gather, this plague is not general, its fancy being apparently for especially situated estates. You know the impenetrable silence of everything before a big storm? How at last you almost strain your ears to catch the rustle of a leaf, or the twitter of a bird? Well that is exactly how it is with your South Wynaad "special" as regards news of "tea." A month or two ago I dreamed of long telling paragraphs for the *Madras Times*. The air was full of rumours, and I had no end of enchanting "strictly confidential" whispered into my delighted ears. When my neighbours talked of this and that possibility, I chuckled to myself, and thought about certain estates, and what I knew was going to be done with them and so on. I even mentally planned an "interview" with the manager of our "Central Factory," and how I would describe him as such a splendid genial fellow, and all that, and tell you all about the machinery and the penetrating, intoxicating odour of the hot tea and so on. Now, I fall run down to the lowest depths of humiliation, for here is May, and oh! Mr Editor, be merciful for like the rustic lover "I have got nuthin' to say." Absolutely nothing further is heard at present on the tea subject, and certainly nothing practical in the way of planting is likely to occur this year. It is a terrible pity that so much splendid possibilities should be thus ruthlessly wasted. However, to revert to my former *smile*, perhaps it may be only the silence before the storm, and I may yet gladly record jubilee days for poor old Wynaad.

The Woodlands Estate, I note, has passed hands since I last wrote and became the property of a "perfect stranger." The management, however, remains the same.—*Madras Times*, May 10th.

THE INDIAN COTTON CROP OF 1891-92.

The final Memorandum on the Indian cotton crop of 1891-92, which we have just received, shows that throughout the reporting Provinces the season was exceptionally unfavourable to the crop and that both area and output have in consequence fallen off largely. The Punjab crop is estimated at 41 per cent. less in area and 36 per cent. less in output than in 1890-91, itself an unfavourable year, and is stated to be the lowest crop on record. In the North-Western Provinces and Oudh the deficiency is 23 per cent. in area and 42 per cent. in output, and in Madras it is 21 and 30 per cent., respectively. In the remaining Provinces the influence of the adverse season on the area returns is less marked. The falling off in production due to the diminished area is aggravated by the lower yield per acre, which is disclosed in the estimates of output, which in Bombay is put at 36, in the Central Provinces at 35, and in Berar at 15 per cent. less than last year's. The general result for the seven reporting Provinces is that the area stands at a little over 11 million acres against 13 million acres in the previous year and an average acreage of over 12 millions. The forecast of production is 1,380,000 bales of 400 lb. each against 2,031,000 in 1890-91, and an average of 2,185,000. Taking the average value of a bale at Rs100, the money equivalent of the deficiency on the crop of 1891-92, as compared with the normal, is, roughly, 112 millions of rupees, or about 74 per cent of the average annual exports of cotton to foreign countries, and over 33 per cent of its estimated average production.

Sir Edward Buck remarks that the export trade in Indian cotton is not progressive and fluctuates largely; so also does the output, the cotton plant being very susceptible to the influence of unfavourable seasons and the attacks of insects. But al-

though complaints of adulteration have been some what loud and frequent of late years, the trade returns afford no evidence of any marked decline in either demand or supply. Indeed, taking into consideration the annually increasing consumption of Indian mills, there is, he says, good reason to conclude that the total production of raw cotton has, on the whole, increased rather than diminished. What has taken place is a diversion of the Indian exports from the markets of the United Kingdom to those of other European countries, among which Italy, Belgium, Germany, Austria, and France are the principal customers. As the year for which trade returns are compiled ends on the 31st March, the full effect of the present unfavourable harvest will not, Sir Edward Buck writes, be apparent till 1892-93, the traffic returns of which may be expected to show a large falling-off. The exports by sea to foreign countries during 1891-92 will also in all probability be much less satisfactory than those of the preceding year, as the harvest of 1890-91 was unfavourable, though not nearly to the same extent as the present one. The total foreign exports registered during the first ten months of 1891-92 (ending 31st January 1892) amounted to 931,230 bales, against 1,207,360 and 1,238,160 in the corresponding periods of 1889-90 and 1890-91.—*Madras Mail*.

TEA IN CHINA.—The reports from China regarding tea continue to be more and more gloomy. The *Foochow Echo* of 23rd April has the following:—

From a native source we learn that four Chinese millionaires (?) of Hinghua have conceived the idea of substituting cotton for tea in several districts, and their agents are now busy sounding the country-people as to whether they will co-operate with them. Our informant states that the scheme is well thought of generally, if only the Government will assist the project (as before) instead of obstructing it of which there seems to be some dread. News of the great falling off in advances to the teaan this season seems to have reached the tea districts npace, since we are already assured that growers, instead of allowing all their first pickings to lie at the mercy of the few who may be in a position to buy it on the spot, intend sending large quantities of it down to the Foochow dealers to sell to the local pickers. As it is generally understood that the sooner tea is cured and packed after picking the better, foreign tea buyers will not learn of this new departure with much satisfaction. Nor will the up-country buyers be best pleased if this move is carried out to the extent talked of; they had planned to corner the growers, but, if we may use a sporting expression, the growers are going to hedge. Between the two factions, foreigners may be the gainers in the end as far as price is concerned. Yet another large Chinese Bank has now been started over the bridge, making four new ones since the commencement of the new year. Considering the admitted unsoundness of business all round, we learn of this with some surprise. The capital of this new bank is said to be considerable, and they will have to use it though in what way is not very clear. That they will have applications for loans from disappointed teaan is certain, but they must have more faith in the future of tea if they accept such men as customers, when the older banks, well acquainted with the business, decline to loan money to them. Of course there are several other articles of merchandise dealt in at the port on a very large scale, but the trade is in an unsound state, and as the bankers have been sufferers with the traders themselves, it is astonishing to hear of so many new banks starting.

We also read:—
A correspondent at Hankow, writing to the *N. O. Daily News* on the 26th ult., says:—'Torrential rains here: bad look out for the tea, as this is just the picking time. Rain at the picking season means "bar" and too old leaf, while if this season's crop should turn out a bad one, it will put the finish on Obiea tea.' According to reports in the native papers, this year's tea crop is going to be both bad and small, a fact which

is attributed to the bad weather, and in consequence of this the price of the first leaf has risen already. The *Shenpao's* Weichow correspondent describes the yield of tea this year, in the Pieryung district, as being very bad. Owing to the unusual cold and incessant rain the tea plants have been much stunted and the crop this season is estimated to be only half of what was produced last year. Tea merchants who have gone to the mountains to purchase tea are paying high prices. For the best quality they are giving 50 dollars per picul and for an inferior kind 30 dollars per picul is charged.

COFFEE IN JAMAICA.—Sir Nicholas Laws, it is said, was the first person who planted coffee in Jamaica, but dying three years afterwards he did not see the cultivation make any considerable progress. In 1732 several planters and merchants subscribed £220,103 as a fund for defraying the charges of soliciting an act of Parliament for lowering the inland duty upon the importation of coffee from Jamaica into Great Britain, which at that time was £10 per cwt. That year the duty was reduced from 2s to 18d per pound producing a revenue of £10,000 per annum. In 1752 the export from Jamaica was 500 cwt, in 1755 it was 4,000 cwt. in 1891 it was over 75,000 cwt. *Madras Times*.

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE, COLOMBO.

Added as Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for June:—

INSECTICIDES AND FUNGICIDES, AND THE APPARATUS FOR DISTRIBUTING THEM.

ANY insects and fungi, destructive to cereals, from the nature and time of their attack, cannot be directly dealt with, and must be left to their destructive works

though there are indirect means of preventing their appearance. In the case of the fungi known as smut (*Ustilago Segetum*) and rust (*Uredo-graminis*), nothing has yet been found of avail after they have appeared, though sulphate of copper, applied to the plants when young, will most probably keep them off.

Wireworms, the grubs of the click beetle, (*Elatер lineatus*) can be hindered in their destructive work by dressings of gas-lime, at the rate of 10 cwt. per acre ploughed into the land. Top-dressings put on the crops at an early stage, consisting of soot, from 20 to 40 bushels per acre, or guano, from $1\frac{1}{2}$ to 3 cwt. per acre, or nitrate of soda, 1 to 2 cwt. per acre, have been found valuable, acting as plant stimulants, as well as by keeping the insects off the plants. Salt put on at the rate of from 4 to 6 cwt. per acre is also useful as tending to make the neighbourhood of the plants unpleasant. After all these applications the land should be well rolled.

In some seasons the plant louse (*Aphis granaria*) causes much harm, first by exhausting the juices of cereals, and later by getting into the ear and doing much mischief. When it is seen that these aphides are on the plants in large numbers, it is well to apply a wash of soft soap and quassia, in the proportion of 7 lbs. of soap to an

infusion made from 6 or 7 lbs. of quassia chips to 100 gallons of water. This should be sprayed on with an efficient spraying machine before the plants get too high. Again, paraffin solution might be used, made of 3 quarts of paraffin to 100 gallons of water, with 4 or 5 lbs. of soft soap, or paraffin pure and simple distributed at the rate of from 2 to 3 gallons per acre. Aphides multiply with incredible rapidity; early dressings may therefore effectually prevent a bad attack.

For the eel-worm (*Tylenchus devastatrix*) which makes the bases of the stems of cereals swell, and plants unhealthy and unproductive, applications of sulphate of potash, at from 1 to $2\frac{1}{2}$ cwt. per acre, have been found most useful, and a mixture of 2 cwt. superphosphate, and 1 cwt. each of sulphate of potash and sulphate of ammonia per acre have been found of benefit.

Almost similar remedies to those employed against wire-worms may be used for the grubs of the daddy-long legs (*Tipula oleracea*) and its congeners (*Tipula maculosa* &c.) when they infect cereals. All these dressings of manure and preventive substances may be put in by the hand, or with ordinary broadcasting machines, or with the Strawsonizer, whose powers of distribution are generally acknowledged. One great advantage of this distributor is that as little as half a bushel of powdered substance can be put on per acre, and as small a quantity of liquid as a gallon per acre if desired. In many cases of insect and fungoid attacks upon plants, the great object in spraying is to spread the obnoxious substance all over the leaves in the form of a mist or dense fog. A very small quantity suffices to make the plants objectionable to insects and fungi.

For the mustard beetle or black jack (*Phædon betulae*) the following is serviceable: 5 lbs. soft soap well dissolved in water, extract of 5 lbs. of quassia boiled, 100 gallons water. Paraffin and

soft soap compositions, and quassia and soft soap washes have been tried with advantage to prevent and check the onion fly (*Anthomyia ceparum*), the celery fly (*Tephritis onopordinis*), the carrot fly (*Psila rosæ*), all of which work great destruction in vegetable gardens. These remedies may be put on with garden engines fitted with nozzles like the Rily, the helmet spray, the Clinax, and Stott nozzles, or with the "knapsack" machine, of which there are several patterns in use. The best of these seems to be the Eclair which is about 2 feet high, and consists of a copper reservoir, or vessel, holding 26 pints, made to fit on to the operator's back, being fastened there with straps like a knapsack. A rod traverses the lower part of the reservoir inside, being worked by a lever with the operator's hand. This does not move a piston as in ordinary pumps, but acts upon an Indianrubber diaphragm, by whose sucking action the liquid is forced through the delivery tube with great force. With the Vermorel or Rily nozzle the liquid can be delivered in the finest spray, or almost in single jets, and in any direction. For high trees the delivery hose can be lengthened by being attached to a light wooden or cane pole and directed by a boy. The machine will throw a spray from 20 to 25 feet and a jet 30 feet high. It weighs about 40 lbs. when full and costs 35 shillings. The Eclair is sold in London by Messrs. Clark & Co., Windsor Chambers, 20, Great St., Helens, E. C.

The onion crop—a source of much profit—also suffers greatly from the onion mildew (*Peronospora Schleideniana*). Sulphate of copper solutions will prevent this attack if put on just as the bulbs begin to swell. In preparing, dissolve the sulphate of copper (5 lbs.) in a wooden vessel in 3 gallons of boiling water; in another vessel the lime (2½ lbs. of quicklime) is put with 4 or 5 pints of water, and when slaked 4 gallons of water are added and the whole well stirred. This is then poured into the tub containing the sulphate of copper, being passed through a sieve to keep back the particles of lime. The whole is well stirred and water to make up 22 gallons is added.

Another and a weaker preparation is as follows:—The sulphate of copper (3 lbs.) is dissolved in cold water by hanging it in a coarse bag or basket in a tub. In a separate tank the quicklime (1 lb.) is slaked and passed through a sieve and put into the tub with the sulphate of copper, and the whole well-stirred. Water to make up 20 gallons is added. The Tomato is much affected in some seasons by a fungus of the family *Peronosporaceæ*, and sulphate of copper preparations have been proved to be efficacious against this. The solutions may be put on with the Eclair machine. Sulphate of copper may be used in the form of a powder for mildews (fungi) of various kinds. A good preparation of this consists of sulphur 50 parts, quicklime 3, sulphate of copper 10, coal dust very finely crushed 37 parts.

Another powder (the Skawinski, obtainable of the manufacturer of that name, at Lesparre, Medoc, France, for about 10 shillings per cwt.) active against fungoid attack, and used for vine mildew, is composed of 40 lbs. sulphate of copper, 6 lbs. quicklime, 154 lbs. coal dust finely ground. This may be put on with a soufflet or

bellows which is a very useful means of distributing powders on a small scale for insect and fungoid attacks. A handy pail engine for small areas is Snow's patent universal garden engine, which may be fixed in any ordinary pail. The pump is very strong, forcing a powerful jet either in a single stream or in a thick fog. It is most easily worked.

The helmet spray before referred to, envelopes plants in the densest mist; the delivery can be regulated by turning a screw.

OCCASIONAL NOTES.

The stud bull at the School of Agriculture is available for service; charge £2.50 per head; arrangements as to date &c. should be made by letter.

We have received from the Lawes' Chemical Manure Company one bag each of their special manures for cotton, paddy and cereals, and for grass and leguminous crops, with the request that we will experiment with them on our grounds. We have also received from Messrs. Sutton & Sons, the well-known seedsmen of Reading, a box containing samples of the following seed: Lucerne, Common Sainfoin, Kidney Vetch, Hungarian Forage grass, Bromus Schroederi, Giant Caragua Maize, Sorghum Vulgare, and Sorghum Saccharatum, Permanent pasture grasses and clovers, and strong-growing grasses and clovers for 3 or 4 years lay.

Mr. W. A. de Silva, Assistant Master at the School of Agriculture, left for Bombay on the 12th of May, with a view to studying Veterinary Science at the Bombay Veterinary College. Mr. Silva, who holds a Government Scholarship, expects to be away for 3 years, at the end of which time he will return to the School.

Mr. Mendis, an old boy of this school, who has been in the employ of Mr. Clovis de Silva of Moratuwa, on a coconut property in Kegalle district, has just been transferred to a tea estate belonging to the same proprietor in Alutgama.

Mr. Lye, the Veterinary Surgeon, will commence his course of lectures to the Agricultural Students in July, after the vacation. Since his arrival, Mr. Lye has been enquiring into the epizootic disease commonly known as "Murrain," and for this purpose spent a few days in the Matale district, and has advised a course of medical treatment which, we believe, is being adopted at present in the district named.

Some months ago a writer in the *Ceylon Observer* discussed the question of the protection of birds, and urged that singing birds and those useful to the agriculturist should be protected, while those which damage crops should among others be permitted to be destroyed. In the Indian Museum Notes an attempt has been made to classify Indian birds according to the diets which they affect. Under purely insectivorous birds fall the Cuckoos, Trogons, Rollers, Bee-eaters, Hoopoes, Woodpeckers, Goatsuckers, Swifts, Ground Thrushes, Wagtails, Swallows, Hedge-sparrows, Pipits, Redstarts, Robbins, Chats, Fly-catchers, Shrikes, Minirets, Warblers,

Creepers, Drongos or King Crows, Ioras, Green Bulbuls, Ground Babblers, Solitary Babblers, Babbler Thrushes, Crowtits. The following are the birds of mixed diet, partly insectivorous and partly fruit and grain-eaters: Tits, Sibias, White Eyes, Bulbuls, Nuthatches, Orioles, Starlings, Mynas, Thrushes, Finches, Larks, Sunbirds, Flowerpickers, Pheasants, Partridges, Button Quails, Rails, Cranes, Bastards, Waders. The next list comprises birds which live in or near water, their food consisting of fish, frogs and tadpoles, aquatic larvæ of insects, and small animals such as freshwater Crustaceans, Onzels, Kingfishers, Cormorants, Pelicans, Herons, Egrets, Ibis, Ducks, Gulls and Terns. The carnivorous birds are Owls, Vultures and Hawks; Omnivorous:—Crows and Storks; Frugivorous:—Hill Mynahs, Weaver birds, Hornbills, Barbets, Parrots, Pigeons, Sandgrouse.

Very few of the purely insectivorous birds are said to be among those destroyed for plumage or food. It has been observed that in Upper India most small birds breed between April and July, and the four months April, May, June, July practically cover the breeding time of nearly all the birds which require protection. The breeding time of course varies in different climes. If the Director of the Museum would draw up a list of Ceylon birds similar to the above, and note the close seasons of birds, say in the various Provinces, it would greatly aid the Agents of these Provinces in putting into effect what is practically a dead law for the protection of birds in Ceylon.

For human beings the minimum air space consistent with health is 400 cubic feet; horses it is said require double the area, but no less than 1,200 cubic feet have been advised. In England the cubic space of cattle byres varies from 350 to 800 cubic feet. In London 600 cubic feet are required. Dr. Russell, the well-known Sanitarian of Glasgow, has lately been enquiring into this matter, as regards cattle, and after collecting a deal of information on the subject, and discovering probably that the regulations concerning the cubic contents of cattle byres had been framed with imperfect knowledge of the subject, in view of amending the regulations referring to Glasgow, recommends:—1. "That the registration, regulation, and control of byres should be placed in the hands of the sanitary authorities. 2. That in all existing byres the cubic space should be raised to 600 cubic feet. That in all new byres it should be 800 cubic feet, and that the regulations generally, as to lighting, ventilation, cleaning, drainage, and water supply, should be carefully revised, so as to give full effect to the mind of the sanitary authority, and thereby enable them to discharge themselves of the responsibility imposed upon them by the Legislature." If some such system for the inspection and regulation of cattle pens in Ceylon be adopted, it will go a great way towards preventing outbreaks of disease and arresting their progress; for, want of proper ventilation is the chief cause of lowered vitality, of colds and most diseases of the air passages, and of other descriptions of sickness.

KITUL PALM.

THE MODE OF EXTRACTING TODDY.

The processes adopted for the extraction of toddy are to begin with tedious, and a man should go through a complete course of training before he undertakes to practice the art.

When the flower is on the verge of bursting, which often happens before maturity, preparations are made by the toddy drawers to tap the palm. Having tied on a bamboo to the tree, he climbs up with a table knife and a chisel, and commences work by removing the sheaths (hannasus). An oblong-shaped cavity is then cut about a span from the axil of the inflorescence, and "a medicine" compounded of various ingredients is deposited in this cavity. Salt, pepper, ginger, white onion, the roots of ratnatul (*Plumbago rosea*) and the bark of the murunga (*Moringa pterygosperma*) are taken in certain quantities and pounded well in a mortar, first applying a sprinkling of lema or caffer lime juice. After depositing the "medicine" a thick coating of ashes is placed over the mouth of the cavity, and a piece of gunny bag is wrapped round it in several folds and tied with a rope. The flower is then washed with the juice of caffer lime. This done, the apex of the inflorescence is sliced with a knife.

The terms *Kanu Mala* and *Akmala* are used for the flower at different stages of its development. On the second day the man similarly cuts the flower once, and on the third day he cuts it twice (morning and evening), and suspends a vessel from the wounded inflorescence.

If the flower is shaded by leaves so as to prevent the free access of sun, such leaves are cut away. As a preventative against the flower breaking, it is tied to an upper leaf, and in order to keep it motionless, a few stones are suspended.

It is important to observe that there are two kinds of flowers called the *Kohu Mala* and the *Ala Mala* respectively.

The same "medicines" are used for both the flowers, but the most striking difference is, that the *Kohu Mala* always require a dry season, but if there is excessive rain, the flower becomes so hard that the sharpest knife would fail to cut it. There is also every probability of this flower rotting. Any prevailing weather generally suits the *Ala Mala*. Of course there are exceptional instances where this flower also rots, but such cases are very rare. Another difference is that the *Kohu Mala* is not liable to be broken easily, while the *Ala Mala* is very easily broken.

The first yield of sweet toddy is generally rejected. To make sweet toddy ferment and become sour, the roots of eramaniya (*Zizyphus jujuba*), and Sevendera (*Andropogon zeylanicus*) are first sliced into fine pieces, put into the vessel and hung from the flower. Similarly to prevent fermentation, the barks of the *Hal tree* (*Vateria acuminata*) and the leaves of Ankenda (*Aeronychia laurifolia*) are put into the vessels.

I have observed in the case of an extremely fertile tree an uninterrupted flow of the juice, while in trees of ordinary vigour the flow goes on at intervals. A profit of R300 to R400 could safely be calculated (deducting expenses for

medicine which is generally a trifling item) from the sale of produce and preparations. At least 15 flowers arrive at maturity on each tree.*

If a bottle of sweet toddy is left for a few hours, it becomes sour without any application of leaves or barks of trees. But such toddy is said to be not fit for drinking purposes. It is in order to ensure fermentation that the barks of trees &c. are put. During the Kandyan Government, measures were passed to prosecute sellers as well as drinkers of toddy. From a dozen bottles of sweet toddy which fetch at the rate of 2½ cents each, 8 of sour toddy could be prepared, which fetches 5 cents each.† Toddy is said to be efficacious in cases of sore mouth, biliousness, and cutaneous diseases.

Mr. Lee, in his History of Ceylon, says:—"There is another disease called the Beri-beri, to which Europeans are very subject; it is a sort of cramp so very violent that it prostrates those who are attacked by it, and the diseased part might be cut with a knife without causing any pain. The best remedy is to eat pork and biscuit, to drink palm-wine or toddy, and to smoke; three or four months living in this manner cures the patient entirely; on this account the Captain-General Antonio de Mascarenhes, by the physicians' advice, issued an order for every one to smoke in the camp, and to give a good example, he adopted the practice himself first, and after that time the disease was far less prevalent."

T. B. P. KEHELPANNAJA.

(To be continued.)

NOTES FROM A TRAVELLER'S DIARY.

I have just had a run over a large area of the Province of Uva. By far the most interesting place I visited in the province was the Happy Valley Industrial and Reformatory Schools. I alluded to this Institution in some of my previous notes, but I was then able to say very little. After the return of its founder, the Rev. S. Langdon, from England, the Institution has put on fresh vigour, and the way in which the work is now carried on is all that could be desired, and is sure to elicit popular applause.

The most interesting part of the Institution is the Reformatory School where about 40 juvenile offenders are at present undergoing sentence of detention. Agricultural labour, dairy farming, poultry-keeping, tailoring, &c. are the principal industries. The dairy farm is the best that I have as yet seen in the island. A fine lot of selected poultry is kept, and the eggs are hatched by the artificial mode of incubation. Curiously, the head juvenile offender at the Reformatory (*Marsal* by name) who is about 11 years of age, is a boy who was once charged before the Police Magistrate of Colombo with stealing arrowroot from an experimental plot at the Colombo School of Agriculture. He was,

* The racemes are attacked by beetles, while the toddy is drunk by bats. Great damage is done in this way to trees.

† In some parts of the Kandyan Districts vinogar is also prepared from toddy.

however, let off with a warning, but has subsequently been sent to the Reformatory for stealing some clothes in Colombo. This boy is now the favourite of the place, has forgotten all his thieving propensities, and I am assured that he has thoroughly reformed. He learns dairy farming and gardening, and seemed to be an expert in making butter and cream, and I would not be surprised if he be some day called to the Colombo School of Agriculture as a dairy expert.

A large area of land at the Happy Valley has been put under ten experiments in the cultivation of fruit, paddy, tobacco and various other crops are also being carried on. It would be well if experiments in the cultivation of barley are also started on a somewhat large scale.

I am surprised that the cultivation of ginger does not attract the attention it deserves of the goiyias of Uva. A large quantity of the ginger consumed in the Province, I think, is brought from the Western Province. During the late epidemic of cholera, in some parts of the Province, a pound of ginger was sold for from R1 to R2. The lowest price of a pound of ginger at Badulla on any day is 12½ cents.

The patanas of Uva may in some respects be compared to some of the owita lands we often meet with in the Western Province, covered with rank grass. Bracken fern is commonly met with on the patanas, the presence of which is supposed to indicate fertility of the soil; the daffodil orchid is also common, and it is easily recognised by the yellow colour of its flowers which appear in the months of February and March, peeping through the grass on their long slender stalks from among the patana grass.

The country around Happy Valley seems to have once been thickly populated, and was probably the site of Portuguese encampments during the struggles they had with the Sinhalese kings. The names of places such as Halatutonne (rice store plain), Haldummulle, (the corner at which rice was distributed) and Batigangoda (the villages in which the rice was cooked and served) bear out these facts.

CROTON TIGLIUM.

Some time ago a writer in the *Times of Ceylon* called attention to the danger in planting croton-oil trees among tea bushes, as was then the case on many places in the Matale district, since it was feared that while plucking the leaves from the latter, some leaves of the former might accidentally fall into the baskets and be manufactured into tea. Natives have a dread of the croton tree, as its poisonous properties are so well known to them, that they fear even to pass under its shadow. Even native medical practitioners, in prescribing the oil obtained from the seed as a purgative, use only a very small quantity, the dose for an adult being about half a grain or only a drop which is rubbed on a betel leaf and given to the patient to be chewed and swallowed. Some Sinhalese cartmen at

Wattagama came to grief by eating rice that had been cooked over a fire ignited with croton sticks. But the tea planters of Matale took no heed of this warning, till at last people in England began to make enquiries regarding the laxative quality of certain brands of tea sent from Ceylon, by the use of which several persons would seem to have taken ill. Shortly after this almost all the croton trees on tea estates disappeared. Planters who did not go in for tea were more fortunate and allowed their croton trees to remain, and at the present day are making some profit, as since of late there has been a demand for this product. The writer being one of these fortunates might be congratulated for his wisdom, but if the reader wishes for an instance where it was folly to be wise, he need only be told that not long ago he (the writer) had the misfortune to lose a good servicable horse which died after three days' violent purging, supposed to have been caused by its having eaten some croton leaves from trees growing by the roadside. Sometimes this tree is infected with a kind of caterpillar which drops to the ground in large numbers when the tree is shaken; and fowls have been seen to gorge themselves with the grub. What seems strange is that these birds were never known to have suffered any bad effects afterwards; nor is it known that any people have been inconvenienced by eating the fowls in question. But those who possess poultry ought to prevent them eating the croton oil seed, as they do eat it when they can get at it, and then become stupefied, *pirouette*, and gyrate like a spinning top till they drop dead. This potency of the seed does not however appear to affect the ground-doves, very common birds in the island, which feed on it quite freely. No other animals are known to eat either the leaves or the seed. Where domestic troubles arise among those more intelligent animals, the Tamil coolies employed on estates where croton trees still exist, and Ramasamy gives his wife a beating, the latter not infrequently revenges herself by taking a mouthful of the poisonous seed and causes much consternation among her kith and kin, till the usual remedy of bathing the patient in cold water, to counteract the poison, is resorted to. Sometimes purging and vomiting continue for several hours, but ultimately stop after the bath, leaving the mouth much inflamed by the irritating poison, and the throat quite sore. These effects necessitate the patient being kept on milk, butter and sweets for several days, and thus the husband of the victim has to pay rather dearly for his indiscretion!

ALL PRODUCTS.

NITRIFYING FERMENTS OF THE SOIL.

This forms the subject of an instructive article by Mr. J. M. M. Munro, in the *Royal Agricultural Society's Journal*. In 1877, the experiments of Schloesing and Muntz threw an entirely new light on the matter of nitrification, the existence of which was well known to Boussingault as early as 1856, though the process by which nitrification went on was not then understood. The

experiments of 1877 were taken up on the suggestion of Pasteur in 1862, that the oxidation in this case (like that in the conversion of wine into vinegar) might be due to the action of a living ferment and not to simple action of the air. "Fifteen years after this suggestion" says Mr. Munro, "the first experiments confirming it were published, and not until the present year, that is after the lapse of nearly fifteen years more, has the prediction been fully and completely verified by the isolation and separate examination of, at any rate, two of the species of organisms concerned in the process." So slow, in certain cases, is the onward progress of what we are accustomed to regard as the rapid advancing strides of science. A considerable portion of the paper is taken up with the history of what Mr. Munro terms "the hunt after these organisms." Those who worked industriously and followed up the scent were Warrington, Winogradsky, Dr. and Mrs. Frankland, and apparently Mr. Munro himself.

Warrington, summing up the results of his experiments, tells us that all samples of soil taken down to 2 feet in depth provoked nitrification, but that over this depth failures to nitrify increase in number, and at a depth of 6 feet and over, the soil has lost this power. From this and other experiments it would appear to be certain that the first few inches of surface soil contain the ferments in vastly greater proportions than the subsoil. From the soil these ferments get into water, and the power which rivers and wells have of ultimately converting the ammonia of sewage into nitrate of limo (or other base) depends on their presence.

One after another discoveries were made, the last and one of the most important being that of Winogradsky, that the nitrifying ferments have an antagonism to organic matter. Mr. Munro says that the importance of this discovery is very great; it reveals an entirely new property of living things, that of building up from the carbon of mineral carbonates and the nitrogen of ammonia, the complicated albuminoid and other organic constituents of living cells. It appears that about 35 parts of nitrogen in the form of ammonia have to be oxidised to a nitrate for one part of carbon taken in as food by the ferment: and it is the heat evolved by this large oxidation that furnishes the force necessary to effect the decomposition of the carbonate.

Mr. Munro concludes his paper with the following important reflection:—The practical point should not be lost sight of, that nitrates are destroyed much more easily and much faster than they can be formed. A free supply of air above all things favours their preservation, whilst the presence of organic matter in the absence of air is certain under natural conditions to result in their destruction. This destructive work, we are told, is also brought about by microbes, and is a property common to a great number of different species. Some of these are capable of destroying in a few days as much nitrate as is formed in months or years. Fortunately, the activity of these baneful species can always be kept in abeyance by the aëration of the soil brought about by drainage and good tillage.

SUBSTANCES OF MANURIAL VALUE.

It has often been asked how the ammoniacal liquor from gas works, a byproduct in the process of purifying coal gas, may be used for agricultural purposes. Griffiths, in his treatise on manures, says that gas liquor is essentially an impure solution of carbonate and acetate of ammonia. As gas liquor is of various degrees of strength, the amount of water to be added to it before applying to the land varies also. As a rule, ammoniacal liquor should be diluted with 4 or 5 times its bulk of water. For grass land the manure can be applied by means of a water cart. In very dry weather gas liquor burns up grass, but on the first appearance of the rains, the herbage will again spring up with increased luxuriance. Ammoniacal liquor has also proved a valuable fertilizer for cereal crops growing on clayey soils.

Another way suggested by Dr. Griffiths for utilizing gas liquor is to absorb it by means of saw dust, peat or charcoal (and we might add coir dust), and then to add bono dust to the mixture.

Gas liquor is said to keep off flies and slugs, and it also promotes the fermentation of saw dust, peat, and similar vegetable substances. It is thus used for preparing composts. The addition of dilute sulphuric acid to ammoniacal liquor till it shows no alkaline reaction with red litmus paper, fixes the ammonia as a sulphate.

In an article on the agricultural value of shoddy or woolen waste, Mr. John Hughes says: "Quite recently, in Ceylon, shoddy (manufactured into a very fine powder by treatment with sulphuric acid) has been tried as a manure for the tea plantations; and for these, bearing in mind its richness in organic nitrogen, it promises to be an excellent fertiliser, if only it be properly applied and of good quality." This is a very important qualification, for shoddy is generally of very variable composition, containing cotton and other substances of little or no value, which, moreover, sometimes deter the action of the manures. When very greasy, shoddy is of little value; if consisting of pure wool, it contains a large proportion of nitrogen, and should dissolve under the action of caustic soda. Shoddy as got from woolen mills contains from 2 to 8 % of nitrogen and is generally very greasy: acted upon by sulphuric acid and dried it falls as a powder. Of leather and shoddy Dr. Aitkin says: "Of no value unless they are dissolved." The latter is used by manure manufacturers as a source of ammonia in dissolved manures, and it is capable of yielding from 5 to 10 % of ammonia, but is said to be unsuitable for direct application. The following points should therefore be considered in comparing the merits of shoddy and farmyard manure:—Whether the shoddy consists of pure wool, containing from 7 to 8 % of ammonia and not more than 20 % of water, whether the ingredients are in a suitable condition, and what would be the value of shoddy sold at £3 per ton after being brought into a state convenient for application, and after allowance is made for freight &c. at the present rate of exchange. It will also have to be considered when the calculation according to Mr. Hughes' method is made, whether the saving of

£3 in England by the use of shoddy in place of cattle manure could be effected here under the circumstances just mentioned, and with the fact in view that 1 ton of cattle manure does not cost anything like 7s. 6d. or its equivalent in Rupees in Ceylon.

The value of dried blood in England is about £8 per ton. The nitrogen is in the form of albumen, and is capable of yielding from 12 to 16 per cent of ammonia. "Dried blood," says Warrington, "is an excellent manure, containing 10 to 13 per cent of nitrogen."

Horn dust or keronikon sells in England for about £7 7s. It is capable of yielding from 16 to 18 per cent of ammonia. When in the form of fine dust it decomposes easily and is a good nitrogenous manure even for cereals. When in the form of chips or coarse shavings horn decomposes but slowly.

GENERAL ITEMS.

A simple process for preparing bees-wax is to reduce the comb to the smallest compass, tying the same in a piece of muslin or similar fine material, and placing in a vessel of boiling water, attaching a weight to the bag to keep it some distance below the surface. After boiling for half an hour or so, allow to cool, when the wax will be found as a solid cake on the surface, the impurities being left in the strainer. Or the rough comb may be placed in a vessel of water, and after boiling a short time the whole may be poured through some straining medium placed over another receptacle, where the wax may be left to cool as above. As the wax lightest in colour will be the most valuable, the combs should be sorted before boiling.

Drury mentions the fact that *Valisneria Spiralis* and *Hydrilla Verticillata* are used in India in the process of sugar refining. It is said that sugar refined in the ordinary way is rendered still purer and whiter by covering it with the moist leaves of these succulent aquatic plants, the moisture from which drains slowly through the sugar and carries with it the dark-coloured molasses. After several days the leaves are removed and the upper part of the sugar, which has been most purified, is taken away and dried in the sun. Fresh leaves are then added, by which another layer of sugar is whitened in like manner, and the operation is repeated until the whole mass is refined.

Wight, writing in 1839, of Cocon says:—This is a native of America, and has been introduced into India. Hitherto our attempts at culture have not been very successful, but I saw very thriving trees at Courtallum, and there is one at Palamcottah which annually bears a crop of fruit, and gives promise that it might be increased. I attempted to take grafts from that tree, and also to propagate by slips and gooties, but failed in both attempts. . . . I presume the most probable tracts of country in India for commencing its cultivation on a considerable scale, would be the high and cool tableland of Mysore, in plantations well sheltered, and

still further kept cool and damp by being made in only partially cleared forests. Wherever such localities are to be found the cocoa may be expected to thrive, and might be introduced with effect and at little charge. On the Malabar Coast, too, where forest lands abound, the humid and insular-like climate would as in the West Indies, where it is very extensively cultivated, counteract the injurious effect of excessive heat and render the chances of success fully equal to those of Mysore. The only drawback to its extended cultivation is the slowness of its growth in the first instance, which, however, is well compensated for by its after duration and productiveness. The fresh virgin soil, the shade, the humid atmosphere of forests recently cleared of their brushwood are all dwelt upon by Humbolt as peculiarly favourable for cocoa plantations, and in such of course they ought to be tried in the first instance until we get the tree acclimatised.

The foundation stone of the Bengal Veterinary Institute was laid last month in a suburb of Calcutta. The *Indian Agriculturist* hopes that this institution will not fall into the same errors as those of the Bombay Veterinary College, of turning a hospital for animals into an infirmary for horses, almost to the exclusion of oxen which are the beasts of burden and of agricultural work in the East. It is also hoped that one of the chief objects of the institute will be to bring Veterinary aid to the cultivator, and that the recommendation of the Cattle Plague Commission of 1871 should be adopted, and "a native agency by which epizootic and other diseases might be properly investigated and treated," formed.

The Chinese and Malays make four kinds of Gambier, viz., Gambier papau, bulat, paku, and dudar. The first two of these are used for chewing, the others for dyeing. Besides these, two uses to which Gambier is put, it is also used for tanning, and is said to give a peculiar gloss to leather not produced by other tanning substances. Next to oak-bark it is the most important tanning material. Again, it is used for strengthening canvas and making it water-proof, as a masticatory, and an astringent in medicine. It has been recommended as a preservative of timber in sea water.

A writer in the *Agricultural Journal* of Cape Colony says that Euphorbia or *Naboom* milk is a sure cure for warts on horses and cattle. Three applications removed a very large wart from the belly of a mare. The same result followed in the case of two heifers with warts,—one with so large a wart that it was thought the animal would have to be killed: three applications effected a cure. Young trees should be tapped for the milk, which, if left standing for a few days becomes hard. It should then be cut fine mixed with a little turpentine or paraffin, and stirred till it gets to a fluid again, ready to rub on. The writer states that some years ago, he saw in a paper that a lady in the Queenstown district, who had a cancer on her breast, got cured by the same remedy. It is unfortunately not stated which

of the Euphorbias is the *Naboom* which is evidently a local name. Most of the plants belonging to this family yield a milk which is more or less corrosive in character. The milk from *E. Antiquorum* (Dalookgass), *E. Tortilis* (Senook guss) and *E. Tirucalli* (Nawa-handi) is used as corrosive fluids for blistering and other purposes by the natives of Ceylon.

Sir Charles Elliott, the Lieutenant-Governor of Bengal, in his last report, referring to the food supply of the Provinces recommends the bulb of *Kesoor* (*Cyperus bulbosus*), the *Chilanthi arisi* of North Ceylon, as an article of diet in case of famine. He states that it is palatable and nutritious, and that a scer of it could be dug in a day, but the *Indian Agriculturist* remarks the whole stock of *kesoor*, which moreover is by no means common in all localities, will thus be exhausted in a few hours. In North Ceylon *Chilanthi arisi* is used as an article of diet, especially in seasons of scarcity. The *Indian Agriculturist* suggest that *Motha* (*C. Rotundus*) the Sinhalese *Kalandooroo* might also be pressed into use in famine times.

According to American experiments, phosphatic manures alone or in combination with nitrogenous fertilisers gave the best results with cotton. Nitrogen and potash separately were of little value, but combined with phosphoric acid doubled the yield.

Mr. Edward Brown in his well-known book on Poultry-keeping, says that the true secret of feeding young chickens is to give a little plain food, and often. Amateurs like to give chickens dainty bits, to be constantly feeding them on rich morsels, with the result that they are often killed by kindness. The plainer the diet they get the better, and anything in the shape of forcing is sure to cause harm. Where death does not result at once, the seeds of disease are sown, and sooner or later these seeds are developed, and trouble is the result. Unless chickens are also fed often, they are very apt to suffer and be stunted through hunger, and also to gorge themselves when the food is placed before them, the latter a state of things very likely to induce disease. They should get a warm feed as soon after daylight as possible, and till a month old should have a meal the last thing at night.

Fish guano, which is manufactured from fish offal brought into a very fine mechanical condition, is said to be the cheapest and best form of guanos. Though the values of ammonia in Peruvian and fish guanos are given in the Highland and Agricultural Societies' scale of charges as 15/ and 10/6 per unit respectively, it is there stated that although such are the commercial values, the agricultural values are probably the same. It would thus appear that fish guano is commercially and agriculturally the cheapest guano, and the fact that superior prices paid for Peruvian and leaboe guanos are to be referred to the antiquity and reputation of the former. The manure is said to have given excellent results when applied to sugarcane, tea, coffee and tobacco, and is suitable for all kinds of crops.
